ISL28271, ISL28272

Dual Micropower, Single Supply, Rail-to-Rail Input and Output (RRIO) Instrumentation Amplifier

The ISL28271 and ISL28272 are dual micropower instrumentation amplifiers (in-amps) optimized for single supply operation over the +2.4V to +5.5V range.

Both devices feature an Input Range Enhancement Circuit (IREC) which maintains CMRR performance for input voltages equal to the positive and negative supply rails. The input signal is capable of swinging 10% above the positive supply rail and to 100mV below the negative supply with only a slight degradation of the CMRR performance. The output operation is rail-to-rail.

The ISL28271 is compensated for a minimum gain of 10 or more. For higher gain applications, the ISL28272 is compensated for a minimum gain of 100. The in-amps have CMOS input devices for maximum input common voltage range. The amplifiers can be operated from one lithium cell or two Ni-Cd batteries.

Ordering Information

PART NUMBER (Note)	PART MARKING	PACKAGE (Pb-free)	PKG. DWG. #

ISL28272INEVAL1Z	Evaluation Platform		

*Add “-T7” suffix for tape and reel. Please refer to TB347 for details on reel specifications.

NOTE: These Intersil Pb-free plastic packaged products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate PLUS ANNEAL - e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Features

- 120µA typical supply current for both channels
- 30pA max input bias current
- 100dB CMRR, PSRR
- 0.7µV/°C offset voltage temperature coefficient
- 180kHz 3dB Bandwidth - ISL28271
- 100kHz 3dB Bandwidth - ISL28272
- 0.5V/µs slew rate
- Single supply operation
- Rail-to-rail input and output (RRIO)
- Input is capable of swinging above V+ and below V- (ground sensing)
- 0.081%1 typical gain error - ISL28271
- -0.19%1 typical gain error - ISL28272
- Pb-free available (RoHS compliant)

Applications

- Battery- or solar-powered systems
- Strain gauge
- Sensor signal conditioning
- Medical devices
- Industrial instrumentations

Application Information

Product Description

The ISL28271 and ISL28272 are dual channel micropower instrumentation amplifiers (in-amps) which deliver rail-to-rail input amplification and rail-to-rail output swing. The in-amps also deliver excellent DC and AC specifications while consuming only about 120µA for both channels. Because the independent pair of feedback terminals set the gain and adjust the output zero level, the ISL28271 and ISL28272 achieve high CMRR regardless of the tolerance of the gain setting resistors. The ISL28271 is internally compensated for a minimum gain of 10. The ISL28272 is internally compensated for a minimum gain of 100.

$\overline{EN}$ pins are available to independently enable or disable a channel. When all channels are off, current consumption is down to typically 4µA.

Input Protection

All input terminals and feedback terminals have internal ESD protection diodes to both positive and negative supply rails, limiting the input voltage to within one diode beyond the supply rails. Input signals originating from low impedance sources should have current limiting resistors in series with the IN+ and IN- pins to prevent damaging currents during power supply sequencing and other transient conditions. The ISL28272 has additional back-to-back diodes across the input terminals and also across the feedback terminals. If overdriving the inputs is necessary, the external input current must never exceed 5mA. External series resistors may be used as an external protection to limit excessive external voltage and current from damaging the inputs. On the other hand, the ISL28271 has no clamps to limit the differential voltage on the input terminals allowing higher differential input voltages at lower gain applications. It is recommended however, that the terminals of the ISL28271 are not overdriven beyond 1V to avoid offset drift.

Input Stage and Input Voltage Range

The input terminals (IN+ and IN-) of the in-amps are a single differential pair of CMOS devices aided by an Input Range Enhancement Circuit, IREC, to increase the headroom of operation of the common-mode input voltage. The feedback terminals (FB+ and FB-) also have a similar topology. As a result, the input common-mode voltage range is rail-to-rail regardless of the feedback terminal settings and regardless of the gain settings. They are able to handle input voltages that are at or slightly beyond the supply and ground sensing making these in-amps well suited for single 5V down to 2.4V supply systems.

The IREC enables rail-to-rail input amplification without the problems usually associated with the dual differential stage topology. The IREC ensures that there are no drastic changes in offset voltage over the entire range of the input. See Input Offset Voltage vs Common-Mode Input Voltage in performance charts. IREC also cures the abrupt change and even reverse polarity of the input bias current over the whole range of input.

Output Stage and Output Voltage Range

A Class AB common-source output stage drives the output. The pair of complementary MOSFET devices drive the output VOUT to within a few millivolts of the supply rails. At a 100kΩ load, the PMOS sources current and pulls the output up to 4mV below the positive supply. The NMOS sinks current and pulls the output down to 4mV above the negative supply, or ground in the case of a single supply operation. The current sinking and sourcing capability are internally limited to 31mA. When disabled, the outputs are in a high impedance state.

Gain Setting

VIN, the potential difference across IN+ and IN-, is replicated (less the input offset voltage) across FB+ and FB-. The function of the in-amp is to maintain the differential voltage across FB- and FB+ equal to IN+ and IN-; (FB- - FB+) = (IN+ - IN-). Consequently, the transfer function can be derived. The in-amp gain is set by two external resistors, the feedback resistor R_F, and the gain resistor R_G.

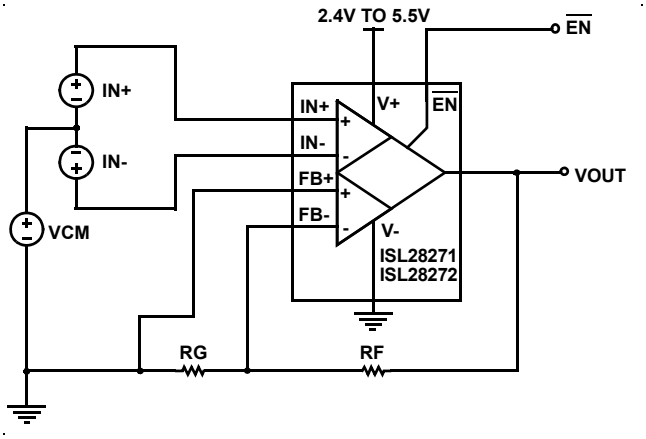

FIGURE 37. GAIN IS SET BY TWO EXTERNAL RESISTORS, R_F AND R_G

$$VIN = IN+ - IN-$$

$$VOUT = \left(1 + \frac{R_F}{R_G}\right) VIN \qquad \text{(EQ. 1)}$$

In Figure 37, the FB+ pin and one end of resistor RG are connected to GND. With this configuration, Equation 1 is only true for a positive swing in VIN; negative input swings will be ignored because the output will be at ground.

Reference Connection

Unlike a three op amp in-amp realization, a finite series resistance seen at the REF terminal does not degrade the high CMRR performance eliminating the need for an additional external buffer amplifier. Figure 38 uses the FB+ pin to provide a high impedance REF terminal.

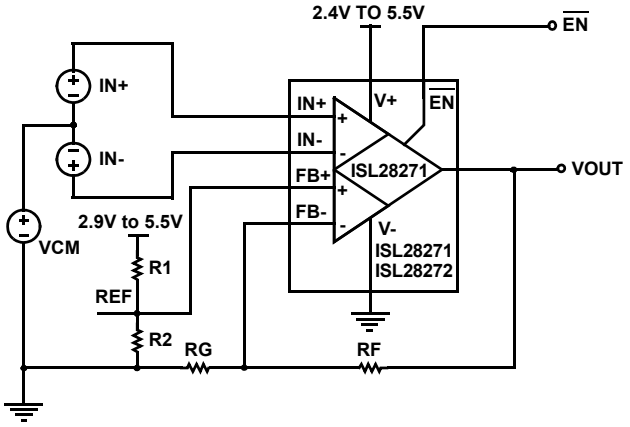

FIGURE 38. GAIN SETTING AND REFERENCE CONNECTION

$$VIN = IN+ - IN-$$

$$VOUT = \left(1 + \frac{R_F}{R_G}\right)(VIN) + \left(1 + \frac{R_F}{R_G}\right)(VREF) \quad \text{(EQ. 2)}$$

The FB+ pin is used as a REF terminal to center or to adjust the output. Because the FB+ pin is a high impedance input, an economical resistor divider can be used to set the voltage at the REF terminal without degrading or affecting the CMRR performance. Any voltage applied to the REF terminal will shift VOUT by VREF times the closed loop gain, which is set by resistors R_F and R_G. See Figure 38.

The FB+ pin can also be connected to the other end of resistor, R_G. See Figure 39. Keeping the basic concept that the in-amp maintains constant differential voltage across the input terminals and feedback terminals (FB- - FB+) = (IN+ - IN-), the transfer function of Figure 39 can be derived.

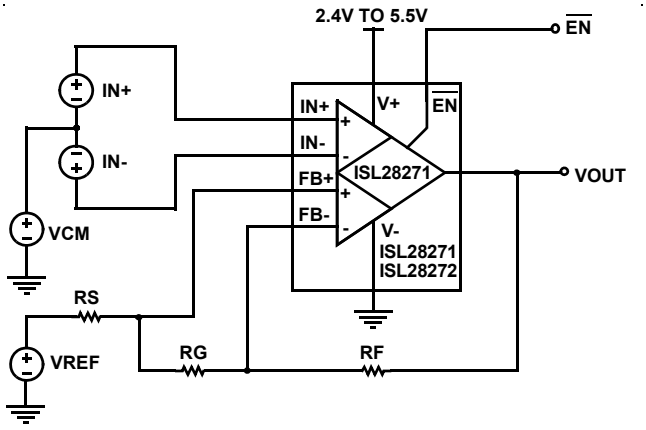

FIGURE 39. REFERENCE CONNECTION WITH AN AVAILABLE VREF

$$VIN = IN+ - IN-$$

$$VOUT = \left[1 + \frac{R_S + R_F}{R_G}\right] + VREF \quad \text{(EQ. 3)}$$

$$VOUT = \left(1 + \frac{R_F}{R_G}\right)(VIN) + (VREF) \quad \text{(EQ. 4)}$$

A finite resistance R_S in series with the VREF source, adds an output offset of VIN*(R_S/R_G). As the series resistance R_S approaches zero, Equation 3 is simplified to Equation 4 for Figure 39. VOUT is simply shifted by an amount VREF.

External Resistor Mismatches

Because of the independent pair of feedback terminals provided by the in-amps, the CMRR is not degraded by any resistor mismatches. Hence, unlike a three op amp and especially a two op amp in-amp realization, the ISL28271 and ISL28272 reduce the cost of external components by allowing the use of 1% or more tolerance resistors without sacrificing CMRR performance. The CMRR will be typically 110dB regardless of the tolerance of the resistors used. Instead, a resistor mismatch results in a higher deviation from the theoretical gain - Gain Error.

Gain Error and Accuracy

The gain error indicated in the “Electrical Specifications” table on page 2 is the inherent gain error alone. The gain error specification listed does not include the gain error contributed by the resistors. There is an additional gain error due to the tolerance of the resistors used. The resulting non-ideal transfer function effectively becomes:

$$VOUT = \left(1 + \frac{R_F}{R_G}\right) \times [1 \pm (E_{RG} + E_{RF} + E_G)] \times VIN \quad \text{(EQ. 5)}$$

Where:

E_{RG} = Tolerance of RG

E_{RF} = Tolerance of RF

E_G = Gain Error of the ISL28271

The term [1 - (E_{RG} +E_{RF} +E_G)] is the deviation from the theoretical gain. Thus, (E_{RG} +E_{RF} +E_G) is the total gain error. For example, if 1% resistors are used, the total gain error would be:

$$TotalGainError = \pm(E_{RG} + E_{RF} + E_G(typical))$$

$$TotalGainError = \pm(0.01 + 0.01 + 0.005) = \pm 2.5\%$$

Disable/Power-Down

The ISL28271 and ISL28272 have an enable/disable pin for each channel. They can be powered down to reduce the supply current to typically 4µA when all channels are off. When disabled, the corresponding output is in a high impedance state. The active low $\overline{EN}$ pin has an internal pull down and hence can be left floating and the in-amp enabled by default. When the $\overline{EN}$ is connected to an external logic, the in-amp will shutdown when $\overline{EN}$ pin is pulled above 2V, and will power up when $\overline{EN}$ bar is pulled below 0.8V.

Unused Channels

The ISL28271 and ISL28272 are Dual channel op amps. If the application only requires one channel when using the ISL28271 or ISL28272, the user must configure the unused channel to prevent it from oscillating. The unused channel will oscillate if the input and output pins are floating. This will result in higher than expected supply currents and possible noise injection into the channel being used. The proper way to prevent this oscillation is to configure the feedback pins (FB+, FB-) with the minimum gain stable values for the amplifier with R_F and R_G resistors and tieing the input terminals to ground (as shown in Figure 40).
