Functional description

The AS7C1024A and AS7C31024A are high performance CMOS 1,048,576-bit Static Random Access Memory (SRAM) devices organized as 131,072 words x 8 bits. It is designed for memory applications where fast data access, low power, and simple interfacing are desired.

Equal address access and cycle times (t_{AA} , t_{RC} , t_{WC}) of 10/12/15/20 ns with output enable access times (t_{OE}) of 5, 6, 7, 8 ns are ideal for high performance applications. Active high and low chip enables ($\overline{CE1}$, CE2) permit easy memory expansion with multiple-bank systems.

When $\overline{CE1}$ is high or CE2 is low the devices enter standby mode. If inputs are still toggling, the device will consume I_{SB} power. If the bus is static, then full standby power is reached (I_{SB1}). For example, the AS7C31024A is guaranteed not to exceed 36mW under nominal full standby conditions. All devices in this family will retain data when V_{CC} is reduced as low as 2.0V.

A write cycle is accomplished by asserting write enable ($\overline{WE}$) and both chip enables ($\overline{CE1}$, CE2). Data on the input pins I/O0-I/O7 is written on the rising edge of $\overline{WE}$ (write cycle 1) or the active-to-inactive edge of $\overline{CE1}$ or CE2 (write cycle 2). To avoid bus contention, external devices should drive I/O pins only after outputs have been disabled with output enable ($\overline{OE}$) or write enable ($\overline{WE}$).

A read cycle is accomplished by asserting output enable ($\overline{OE}$) and both chip enables ($\overline{CE1}$, CE2), with write enable ($\overline{WE}$) high. The chips drive I/O pins with the data word referenced by the input address. When either chip enable is inactive, output enable is inactive, or write enable is active, output drivers stay in high-impedance mode.

Notes

- 1 During V_{CC} power-up, a pull-up resistor to V_{CC} on $\overline{CE1}$ is required to meet I_{SB} specification.
- 2 This parameter is sampled and not 100% tested.
- 3 For test conditions, see AC Test Conditions, Figures A, B, and C.
- 4 t_{CLZ} and t_{CHZ} are specified with $CL = 5pF$, as in Figure C. Transition is measured $\pm 500mV$ from steady-state voltage.
- 5 This parameter is guaranteed, but not 100% tested.
- 6 $\overline{WE}$ is High for read cycle.
- 7 $\overline{CE1}$ and $\overline{OE}$ are Low and $CE2$ is High for read cycle.
- 8 Address valid prior to or coincident with $\overline{CE1}$ transition Low.
- 9 All read cycle timings are referenced from the last valid address to the first transitioning address.
- 10 $\overline{CE1}$ or $\overline{WE}$ must be High or $CE2$ Low during address transitions. Either $\overline{CE1}$ or $\overline{WE}$ asserting high terminates a write cycle.
- 11 All write cycle timings are referenced from the last valid address to the first transitioning address.
- 12 $\overline{CE1}$ and $CE2$ have identical timing.
- 13 $C=30pF$, except all high Z and low Z parameters, $C=5pF$.
