

TDA7460ND

Car radio signal processor

Not For New Design

Features

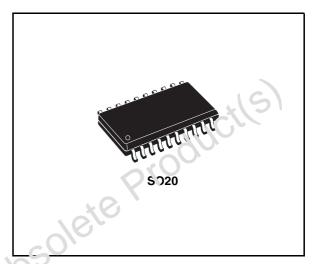

- Device includes audio processor, stereo decoder, noise blanker and multipath detector
- High performance signal processor
- No external components required
- Fully programmable via I²C bus
- Low distortion
- Low noise

Description

The TDA7460ND is a high performance signal processor specifically designed for car radio applications.

The device includes a complete audio processor and a stereo decoder with noise blanker, storeo blend and all signal processing functions necessary for state-of-the-art as well as future car radio systems.

Switched-capacitors design reconique allows to obtain all these features without external components or adjustments.

This means that higher quality and reliability walks alongside an overall cost saving.

The CSP is fully programmable by I²C bus interface allowing to customize key device parameters and especially filter characteristics.

The BICMOS process combined with the optimized signal processing assure low noise and low distortion performances.

3.5 **Audio processor part features**

3.5.1 Input multiplexer

- Fully differential or quasi-differential CD and cassette stereo input
- AM mono or stereo input
- Phone differential or single ended input
- Internal beep with 2 frequencies (selectable)
- Mixable phone and beep signals

3.5.2 Loudness

- First or second order frequency response
- Programmable center frequency and quality factor
- 15 x 1 dB steps
- Selectable flat-mode (constant attenuation)

3.5.3 **Volume control**

- 1 dB attenuator
- Max. gain 20 dB
- Max. attenuation 79 dB
- Soft-step gain control

3.5.4 **Bass control**

- 2nd order frequency response
- asolete Product(s) Center frequency programmable in 4(5) steps
- DC gain programmable
- 7 x 2 dB steps

3.5.5 **Treble control**

- 2nd order frequency response
- Center frequency programmable in 4 steps
- 7 x 2 dB steps

3.5.6 Speaker control

4 independent speaker controls (1 dB steps control range 50 dB)

Mute functions 3.5.7

- Direct mute
- Digitally controlled soft mute with 4 programmable time constants

4 Description of the audio processor part

4.1 Programmable input matrix

The programmable input matrix of the TDA7460ND offers several possibilities to adapt the audioprocessor to the desired application. In to the standard application we have:

CD quasi differential

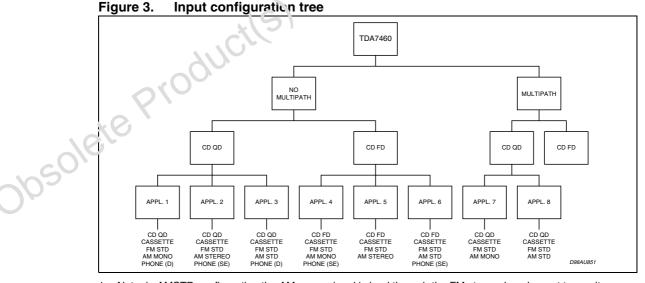

- Cassette stereo
- Phone differential
- AM mono
- Stereo decoder input.

The input matrix can be configured by only 2 bits: bits 3 and 4 of subaddress 0. Sasically the bit of subaddress 13 is fixed by the application and has to be programmed only once at the startup of the IC.

For many configurations the two bits are also fixed during one application (e.g. the standard application) and a change of the input source can be done by bading the first three bits of subaddress 0.

In other configurations for some sources a programming of bit 3 and 4 of subaddress 0 is necessary in addition to the three source selection bits. In every case only the subaddress 0 has to be changed to switch from one source to another.

The following picture shows the input and source programming flow:

 Note: in AMSTD configuration the AM mono signal is lead through the FM stereo decoder part to use its additional filters and high-cut function.

| | | Pin n | umber | | | |
|----------|--------------------|----------------------|---------|--------|---------------------|---|
| Appl. no | 4 | 6 | 7 | 8 | Progran | nming ⁽¹⁾ |
| 1 | CD _{GND} | Phone _{GND} | Phone | AMMONO | Startup: | 0/xxx11xxx |

Table 7. Input and source programming

4.1.1 How to find the right input configuration

The best way to come to the desired configuration may be to go through the application tree from the top to the bottom while making the specific decisions.

This way will lead to one of the six possible applications. Then take the number of the application and go into the pinning table. Here you will find the special pinout as well as the special programming codes for selecting sources.

For example in Appl. 6 the TDA7460ND has to be configured while startup with the databyte 0/xxxx0xxx.

To select the FM, AM or phone source the last five significant bits of subaddress 0 have to be changed, for any other source the last three bits are sufficient (see *Section 7: Data byte specification on page 36*.

^{1.} Syntax 7/. xx11100 means: SUBADDRESS = 0 - DATA BYTE = xxx11100 (x - don't care)

4.1.2 Input stages

Most of the input circuits are the same as in preceding ST audioprocessors with exception of the CD inputs (see *Figure 4*.).In the meantime there are some CD players in the market having a significant high source impedance which affects strongly the common-mode rejection of the normal differential input stage. The additional buffer of the CD input avoids this drawback and offers the full common-mode rejection even with those CD players.

The TDA7460ND can be configured with an additional input; if the AC coupling before the speaker stage is not used (bit 7 in subaddress 5 set to "1") ACINL and ACINR pins can be used as an additional stereo input.

4.1.3 **AutoZero**

In order to reduce the number of pins there is no AC coupling between the In-Gain and the following stage, so that any offset generated by or before the In-Gain stage would be transferred or even amplified to the output.

To avoid that effect a special offset cancellation stage called AutoZero is implemented. To avoid audible clicks the audioprocessor is muted before the loudness stage during this time. In some cases, for example if the µP is executing a refresh cycle of the I²C bus programming, it is not useful to start a new AutoZero action because no new source is selected and an undesired mute would appear at the outputs. For such applications the TDA7460ND could be switched in the "Auto Zero handin" mode (Bit 6 of the subaddress byte). If this bit is set to high, the DATABYTE C caud be loaded without invoking the AutoZero and the old adjustment value remains.

Figure 4. Input stages

4.2 Mixing stage

This stage offers the possibility to mix the internal beep or the phone signal to any other source. Due to the fact that the mixing stage is also located behind the In-Gain stage fine adjustments of the main source level can be done in this way.

4.2.1 Loudness

There are four parameters programmable in the loudness stage (see *Figure 5.*, *Figure 6.* and *Figure 7.*):

- Attenuation
- Center Frequency
- Loudness Q

Flat Mode: in this mode the loudness stage works as a 0 - 15 dB attenuator.

Figure 5. Loudness attenuation @ fc = 400 Hz (second order)

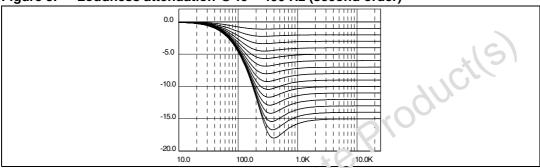

Figure 6. Loudness center frequency @ Atm. = 15 dB (second order)

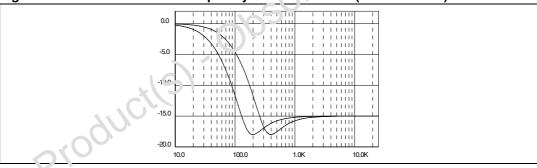

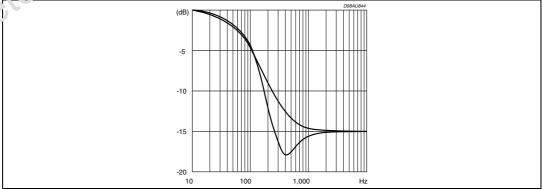

Figure 7. Loudness @ attn. = 15 dB, fc = 400 Hz

4.2.2 Soft mute

The digitally controlled soft mute stage allows muting/demuting the signal with a I²C bus programmable slope. The mute process can either be activated by the soft mute pin or by the I²C bus. The slope is realized in a special S shaped curve to mute slow in the critical regions (see Figure 8.).

For timing purposes the Bit 3 of the I²C bus output register is set to 1 from the start of muting until the end of demuting.

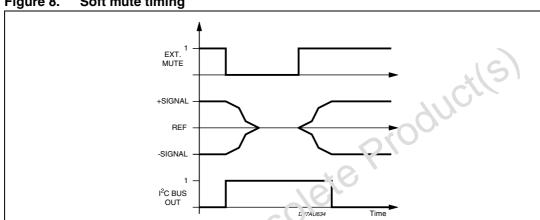

Figure 8. Soft mute timing

Please notice that a started Mute action is always terminated and could not be interrupted by a change of the mute signal.

4.2.3 Soft step volume

When volume level is changed often an audible click appears at the output. The root cause of those clicks could be either a DC offset before the volume stage or the sudden change of the envelope of the audio signal. With the Soft step feature both kinds of clicks could be reduced to a minimum and are no more audible (see Figure 9.).

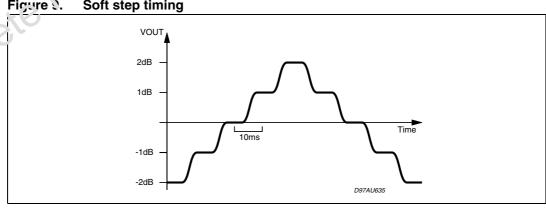

Figure 3. Soft step timing

For steps more than 1 dB the soft step mode should be deactivated because it could generate a 1 dB error during the blend-time

4.2.4 Bass

There are three parameters programmable in the bass stage (see *Figure 10.*, *Figure 11.*, *Figure 12.*, *Figure 13.*):

- Attenuation
- Center Frequency (60, 70, 80 and 100 Hz)
- Quality Factors (1, 1.25, 1.5 and 2)

4.2.5 DC mode

In this mode the DC gain is increased by 4.4 dB. In addition the programmed center frequency and quality factor is decreased by 25% which can be used to reach alternative center frequencies or quality factors.

4.2.6 Treble

There are two parameters programmable in the treble stage (see Figure 14 and Figure 15.):

- Attenuation
- Center Frequency (10, 12.5, 15 and 17.5 kHz).

4.2.7 Speaker attenuator

Due to practical aspects the steps in the specific attenuators are not linear over the full range. At attenuations more than 24 dP this s'eps increase from 1.5 dB to 10 dB (please see Section 7: Data byte specification on page 36).

Figure 10. Bass control @ fc = 80 Hz, Q = 1 Figure 11. Bass center @ Gain = 14 dB, Q = 1

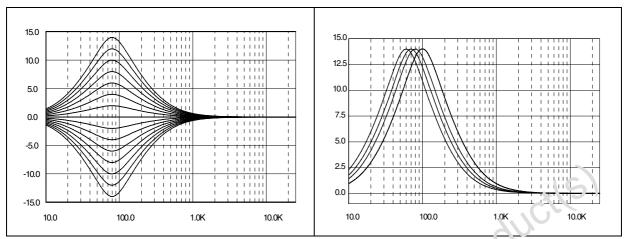

Figure 12. Bass quality factors @ gain = 14 dB, fc = 80 Hz

Figure 13. Bass normal and 5C mode @ Gain = 14 dP, $\pi = 8\tilde{o} \text{ Hz}^{(1)}$

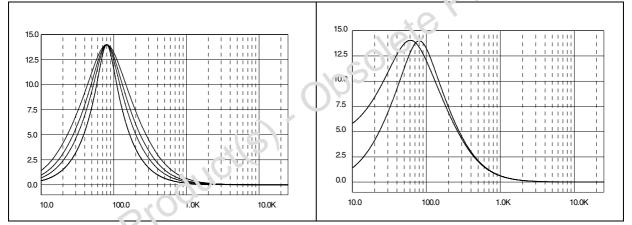

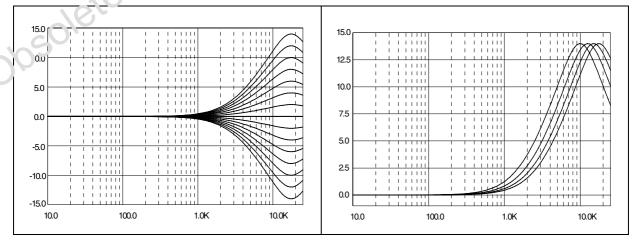

Figure 14. Treble control @ fc = 17.5 KHz

Figure 15. Treble center freq. @ gain = 14 dB

In general the center frequency, Q and DC-mode can be set independently. The exception from this rule is the mode (5/xx1111xx) where the center frequency is set to 150 Hz instead of 100 Hz.

TDA7460ND Stereo decoder part

Stereo decoder part 5

5.1 Stereo decoder feature

- No external components necessary
- PLL with adjustment free fully integrated VCO
- Automatic pilot dependent mono/stereo switching
- Very high suppression of intermodulation and interference
- Programmable Roll-Off compensation
- Dedicated RDS soft mute
- roducils High cut and stereo blend characteristics programmable in a wide range
- Internal noise blanker with threshold controls
- Multipath detector with programmable internal/external influence
- I²C bus control of all necessary functions

Figure 20. Block diagram of the sterce decoder

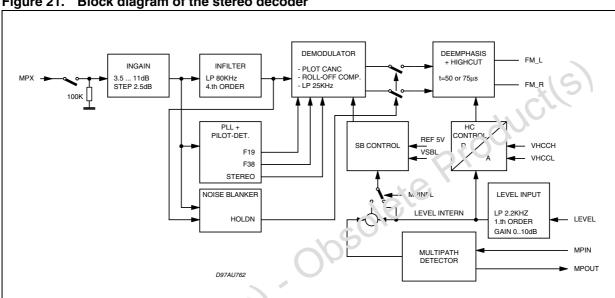

TDA7460ND Stereo decoder part

5.5 **Description of stereo decoder**

The stereo decoder part of the TDA7460ND (see Figure 20.) contains all functions necessary to demodulate the MPX signal like pilot tone dependent mono/stereo switching as well as "stereo blend" and "high cut" functions.

Adaptations like programmable input gain, roll-off compensation, selectable de-emphasis time constant and a programmable fieldstrength input allow to use different IF devices.

Block diagram of the stereo decoder Figure 21.

5.5.1 Stereo decoder mute

The TDA746011D has a fast and easy to control RDS mute function which is a combination of the autilic processor soft mute and the high-ohmic mute of the stereo decoder. If the stereo decode: is selected and a soft mute command is sent (or activated through the SM pin) the tore) decoder will be set automatically to the high-ohmic mute condition after the audio signal has been softmuted.

Hence a checking of alternate frequencies could be performed. To release the system from the mute condition simply the unmute command must be sent: the stereo decoder is unmuted immediately and the audioprocessor is softly unmuted. Fig. 18 shows the output signal V_O as well as the internal stereo decoder mute signal. This influence of Softmute on the stereo decoder mute can be switched off by setting bit 3 of the Softmute byte to "0". A stereo decoder mute command (bit 0, stereo decoder byte set to "1") will set the stereo decoder in any case independently to the high-ohmic mute state.

If any other source than the stereo decoder is selected the decoder remains muted and the MPX pin is connected to Vref to avoid any discharge of the coupling capacitor through leakage currents.

Stereo decoder part TDA7460ND

5.5.2 Input stages

The In gain stage allows to adjust the MPX signal to a magnitude of about 1Vrms internally which is the recommended value. The 4.th order input filter has a corner frequency of 80kHz and is used to attenuate spikes and noise and acts as an anti-aliasing filter for the following switch capacitor filters.

5.5.3 Demodulator

In the demodulator block the left and the right channel are separated from the MPX signal. In this stage also the 19 kHz pilot tone is cancelled. For reaching a high channel separation the TDA7460ND offers an I²C bus programmable roll-off adjustment which is able to compensate the lowpass behavior of the tuner section. If the tuner attenuation at 38kHz is in a range from 20.2% to 31% the TDA7460ND needs no external network before the MPY pin. Within this range an adjustment to obtain at least 40d B channel separation is possible.

The bits for this adjustment are located together with the fieldstrength adjustment in one byte. This gives the possibility to perform an optimization step during the production of the car radio where the channel separation and the fieldstrength control are trimmed.

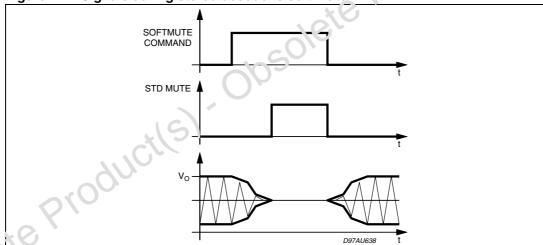

Figure 22. Signals during stereo decoder's soft mute

5.5.4 De-emphasis and high cut

The lowpass filter for the de-emphasis allows to choose between a time constant of 50ms and 75ms (bit D7, Stereo decoder byte).

The high cut control range will be in both cases $t_{HC} = 2 \cdot t_{Deemp}$. Inside the high cut control range (between VHCH and VHCL) the LEVEL signal is converted into a 5 bit word which controls the lowpass time constant between t_{Deemp} ...3 \cdot t_{Deemp} . There by the resolution will remain always 5 bits independently of the absolute voltage range between the VHCH and VHCL values.

The high cut function can be switched off by I²C bus (bit D7, Fieldstrength byte set to "0").

TDA7460ND Stereo decoder part

5.5.5 PLL and pilot tone detector

The PLL has the task to lock on the 19kHz pilotone during a stereo transmission to allow a correct demodulation. The included detector enables the demodulation if the pilot tone reaches the selected pilottone threshold VPTHST. Two different thresholds are available. The detector output (signal STEREO, see *Figure 1: Block diagram*) can be checked by reading the status byte of the TDA7460ND via I²C bus.

5.5.6 Fieldstrength control

The fieldstrength input is used to control the high cut and the stereo blend function. In addition the signal can be also used to control the noise blanker thresholds.

5.5.7 Level input and gain

To suppress undesired high frequency modulation on the high cut and stereo bend function the LEVEL signal is lowpass filtered firstly. The filter is a combination of a 1st order RC lowpass at 53 kHz (working as anti-aliasing filter) and a 1st-order switched capacitor lowpass at 2.2 kHz. The second stage is a programmable gain stage 10 adapt the LEVEL signal internally to different IF.

The gain is widely programmable in 16 steps from 0 dP to 10 dB (step = 0.67 dB). These 4 bits are located together with the roll-off bits in the "Stores decoder Adjustment" byte to simplify a possible adaptation during the production of the carradio.

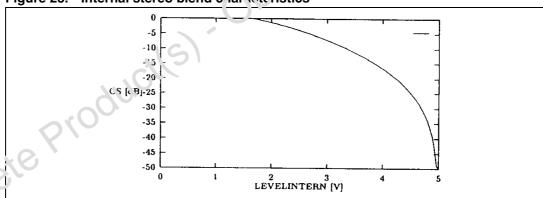

Figure 23. Internal stereo blend characteristics

5.5.8 Stereo blend control

The stereo blend control block converts the internal LEVEL voltage (LEVEL INTERN) into an demodulator compatible analog signal which is used to control the channel separation between 0dB and the maximum separation. Internally this control range has a fixed upper limit which is the internal reference voltage REF5V. The lower limit can be programmed to be 33%, 42%, 50% or 58% of REF5V (see *Figure 24*.).

To adjust the external LEVEL voltage to the internal range two values must be defined: the LEVEL gain L_G and VSBL. To adjust the voltage where the full channel separation is reached (VST) the LEVEL gain LG has to be defined. The following equation can be used to estimate the gain:

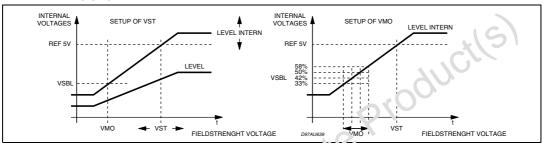

Stereo decoder part TDA7460ND

The gain can be programmed through 4 bits in the "Stereo decoder-Adjustment" byte.

The mono voltage VMO (0 dB channel separation) can be chosen selecting 33, 42, 50 or 58 % of REF5V.All necessary internal reference voltages like REF5V are derived from a bandgap circuit. Therefore they have a temperature coefficient near zero. This is useful if the fieldstrength signal is also temperature compensated.

But most if devices apply a level voltage with a TC of 3300 ppm. The TDA7460ND offers this TC for the reference voltages, too. The TC is selectable with bit D7 of the "stereo decoder adjustment" byte.

Figure 24. Relation between internal and external LEVEL voltage and setup of stereo blend

5.5.9 High cut control

The high cut control setup is similar to the steres blend control setup: the starting point VHCH can be set with 2 bits to be 42 50, 53 or 66% of REF5 V whereas the range can be set to be 17 or 33% of VHCH (see *Figure 25*.).

Figure 25. High cut characteristics

5.6 Functional description of the noise blanker

In the automotive environment the MPX signal is disturbed by spikes produced by the ignition and for example the wiper motor. The aim of the noise blanker part is to cancel the audible influence of the spikes. Therefore the output of the stereo decoder is held at the actual voltage for $40~\mu s$.

In a first stage the spikes must be detected but to avoid a wrong triggering on high frequency (white) noise a complex trigger control is implemented. Behind the trigger stage a pulse former generates the "blanking" pulse. To avoid any crosstalk to the signal path the noise blanker is supplied by his own biasing circuit.

TDA7460ND Stereo decoder part

5.6.1 Trigger path

The incoming MPX signal is highpass filtered, amplified and rectified. This second order highpass-filter has a corner frequency of 140kHz. The rectified signal, RECT, is lowpass filtered to generate a signal called PEAK. Also noise with a frequency 140 kHz increases the PEAK voltage. The PEAK voltage is fed to a threshold generator, which adds to the PEAK voltage a DC dependent threshold VTH. Both signals, RECT and PEAK+VTH are fed to a comparator which triggers a re-triggerable monoflop. The monoflop's output activates the sample-and-hold circuits in the signal path for 40 μs .

The block diagram of the noise blanker is given in Figure 26.

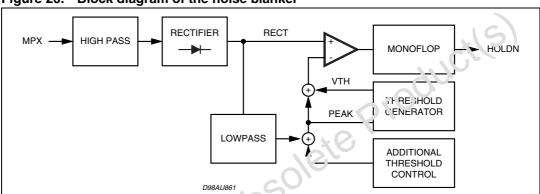

Figure 26. Block diagram of the noise blanker

5.6.2 Automatic noise controlled threshold adjustment (ATC)

There are mainly two independent possibilities for programming the trigger threshold:

- a) the low threshold in 8 steps (bits D0 to D2 of the noise blanker byte)
- b) the noise adjusted threshold in 4 steps (bits D3 and D4 of the noise blanker byte, see *F gure 17*.).

The low threshold is active in combination with a good MPX signal without any noise; the PEAK voltage is less than 1V. The sensitivity in this operation is high.

If the MPX signal is noisy the PEAK voltage increases due to the higher noise, which is also rectified. With increasing of the PEAK voltage the trigger threshold increases, too. This particular gain is programmable in 4 steps (see *Figure 17*.).

5.6.3 Automatic threshold control

Besides the noise controlled threshold adjustment there is an additional possibility for influencing the trigger threshold. It is depending on the stereo blend control.

The point where the MPX signal starts to become noisy is fixed by the RF part. Therefore also the starting point of the normal noise-controlled trigger adjustment is fixed (fig. 16). In some cases the behavior of the noise blanker can be improved by increasing the threshold even in a region of higher fieldstrength. Sometimes a wrong triggering occurs for the MPX signal often shows distortion in this range which can be avoided even if using a low threshold.

Because of the overlap of this range and the range of the stereo/mono transition it can be controlled by stereo blend. This threshold increase is programmable in 3 steps or switched off with bits D0 and D1 of the fieldstrength control byte.

Stereo decoder part TDA7460ND

5.6.4 Over deviation detector

If the system is tuned to stations with a high deviation the noise blanker can trigger on the higher frequencies of the modulation. To avoid this wrong behavior, which causes noise in the output signal, the noise blanker offers a deviation dependent threshold adjustment.

By rectifying the MPX signal a further signal representing the actual deviation is obtained. It is used to increase the PEAK voltage. Offset and gain of this circuit are programmable in 3 steps with the bits D6 and D7 of the stereo decoder byte (the first step turns off the detector, see *Figure 18*.).

5.7 Functional description of the multipath detector

Using the internal detector the audible effects of a multipath condition can be minimized. A multipath condition is detected by rectifying the 19 kHz spectrum in the fieldstrength signal.

Selecting the "internal influence" in the configuration byte, the channel separation is automatically reduced during a multipath condition according to the vol age appearing at the MPOUT pin.

To obtain a optimal performance an adaptation is necessary. Therefore the gain of the 19 kHz bandpass is programmable in four steps as well as the rectifier gain. The attack and decay times can be set by the external capacitor value.

5.8 Test mode

During the test mode which can be activated by setting bit D0 of the testing byte and bit D5 of the subaddress byte to "1" several internal signals are available at the CASSR pin. During this mode the input resistance of 100 kOhm is disconnected from the pin. The internal signals available are shown in the software specification.

6 I²C bus interface description

6.1 Interface protocol

The interface protocol comprises:

- a start condition (S)
- a chip address byte (the LSB bit determines read / write transmission)
- a subaddress byte
- a sequence of data (N-bytes + acknowledge)
- a stop condition (P)

Figure 30. Interface protocol diagram

S = Start:

ACK = Acknowledge;

AZ = AutoZero-Remain;

T = Testing;

I = Auto increment;

P = Stop;

Max clock speed is 500 kbits/s.

The transmitted data is automatically updated after each ACK.

Transmission can be repeated without new chip address.

6.2 Auto increment

If bit I in the subaddress byte is set to "1", the auto increment of the subaddress is enabled.
