Operational Description

The following is an explanation of hardware configuration and operation in relation to the TMP47P840V. The TMP47P840V is the same as the TMP47C640/840 except that an EPROM or OTP is used instead of a built-in mask ROM.

1. Operation mode

The TMP47P840V has an MCU mode and a PROM mode.

1.1 MCU mode

The MCU mode is set by fixing the TEST/VPP pin at the "L" level. Operation in the MCU mode is the same as for the TMP47C640/840, except that the TEST / VPP pin does not have built in pull-down resistor and cannot be used open.

1.1.1 Program memory

The program storage area is the same as for the TMP47C840. Data conversion tables must be set in two locations when using the TMP47P840V to check TMP47C640 operation.

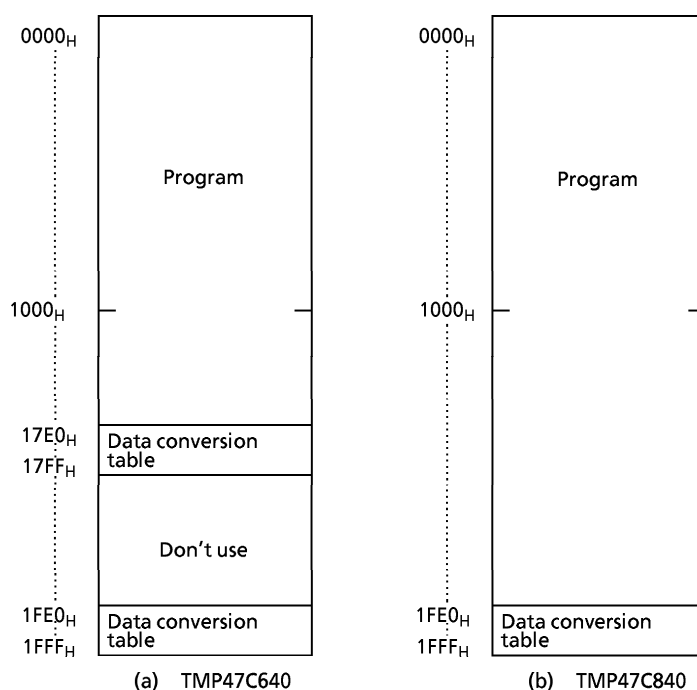

Figure 1-1. Program area

1.1.2 Data memory

The TMP47P840V has 512 × 4-bit data memory bank (RAM).

When using the TMP47P840V as a TMP47C640 evaluator, do not write data to address 80_H and following, even though the bank 1 addresses are 00 to FF_H. There is no necessity to take into consideration a special common function area because one is built in bank 0.

1.1.3 Input/Output circuitry

(1) Control pins

This is the same as for the TMP47C640/840 except that there is no built-in pull-down resistance for the TEST pin.

(2) I/O Ports

The input/output circuit of the TMP47P840V is the same as I/O code 1A of the TMP47C640/840.

External resistance, for example, is required when using as evaluator of other I/O codes (1B, 1C), (Refer to Figure 1.2)

Figure 1-2. I/O code and external circuitry

1.2 PROM mode

The PROM mode is set by setting the $\overline{\text{RESET}}$ and $\overline{\text{HOLD}}$ pins to the "L" level. The PROM mode can be used as a general-purpose PROM writer for program writing and verification. (A high-speed program mode is used set the ROM type the same as for the TMM 2764AD.)

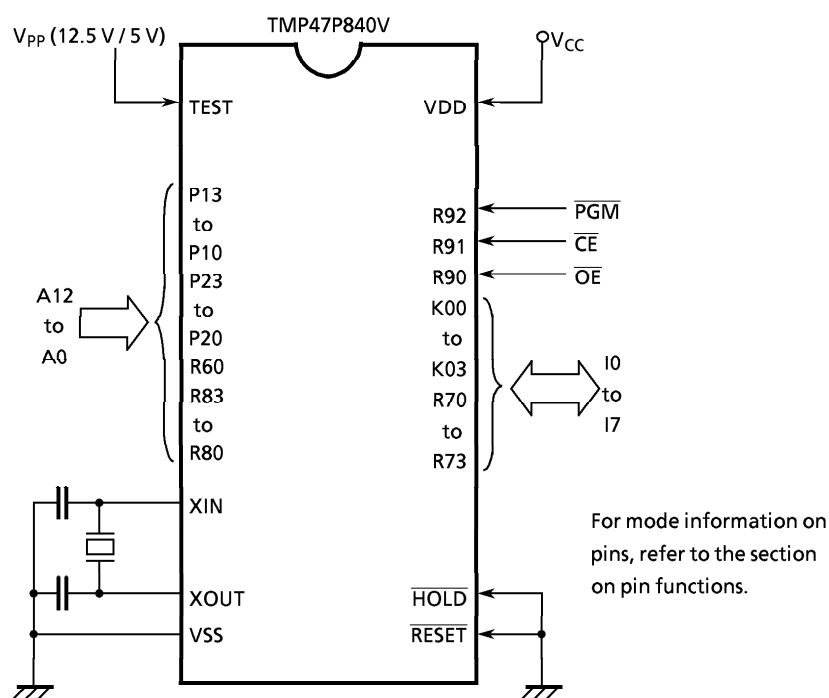

Figure 1-3. Setting for PROM mode

An adapter socket is available for connecting a PROM writer.

- BM1172: TMP47P840VF

1.2.1 High speed programming mode

The device is set up in the high speed programming mode when the programming voltage (12.5 V) is applied to the V_{pp} terminal with $V_{CC} = 6\text{ V}$ and $\overline{\text{PGM}} = V_{IH4}$. The programming is achieved by applying a Single TTL low level 1 ms, pulse the $\overline{\text{PGM}}$ input after addresses and data are stable. Then the programmed data is verified by using program Verify Mode. If the programmed data is not correct, another program pulse of 1 ms is applied and then programmed data is verified. This should be repeated until the program operates correctly (max 25 times). After correctly programming the selected address, one additional program pulse with pulse width 3 times that needed for programming is applied. When programming has been completed, the data in all addresses should be verified with $V_{CC} = V_{pp} = 5\text{ V}$.

Note: The absolute maximum ratings are rated values which must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any absolute maximum rating is exceeded, a device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products which include this device, ensure that no absolute maximum rating value will ever be exceeded.

Note 1: The recommended operating conditions for a device are operating conditions under which it can be guaranteed that the device will operate as specified. If the device is used under operating conditions other than the recommended operating conditions (supply voltage, operating temperature range, specified AC/DC values etc.), malfunction may occur. Thus, when designing products which include this device, ensure that the recommended operating conditions for the device are always adhered to.

Note 2: Input voltage V_{IH3}, V_{IL3}: In the SLOW or HOLD mode.
