

UCD7100 Digital Control Compatible Single Low-Side ± 4 -A MOSFET Driver with Current Sense

1 Features

- Adjustable current limit protection
- 3.3-V, 10-mA internal regulator
- DSP/ μ C compatible inputs
- Single ± 4 -A TrueDrive™ high current driver
- 10-ns typical rise and fall times with 2.2-nF loads
- 25-ns input-to-output propagation delay
- 25-ns current sense to output delay
- Programmable current limit threshold
- Digital output current limit flag
- 4.5-V to 15-V supply voltage range
- Rated from -40°C to 105°C
- Lead(Pb)-free packaging

2 Applications

- Digitally controlled power supplies
- [DC/DC converters](#)
- [Motor controllers](#)
- [Line drivers](#)

3 Description

The UCD7100 device is part of the UCD7K family of digital control compatible drivers for applications that use digital control technology that requires fast local peak current limit protection.

The UCD7100 is a low-side ± 4 -A high-current MOSFET gate driver. It allows the digital power controllers such as UCD9110 or UCD9501 to interface to the power stage in single ended topologies. It provides a cycle-by-cycle current limit function with programmable threshold and a digital output current limit flag which can be monitored by the host controller. With a fast 25-ns cycle-by-cycle current limit protection, the driver can turn off the power stage in the unlikely event that the digital system can not respond to a failure situation in time.

4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision D (October 2014) to Revision E (November 2021)	Page
• Added the UCD7100A device to Device Information	1
• Added the Device Comparison Table	3

5 Description (continued)

For fast switching speeds, the UCD7100 output stage uses the TrueDrive™ output architecture, which delivers rated current of ± 4 A into the gate of a MOSFET during the Miller plateau region of the switching transition. It also includes a 3.3-V, 10-mA linear regulator to provide power to the digital controller.

The UCD7000 driver family is compatible with standard 3.3-V I/O ports of DSPs, Microcontrollers, or ASICs. UCD7100 is offered in a PowerPAD™ HTSSOP-14.

9 Detailed Description

9.1 Overview

The UCD7100 is a member of the UCD7K family of digital control compatible drivers for applications utilizing digital control techniques, or applications requiring fast local peak current limit protection.

The UCD7100 is a low-side ± 4 -A high-current MOSFET gate driver. The UCD7100 allows digital power controllers such as the UCD9110 or UCD9501 to interface to the power stage in single-ended topologies. It provides a cycle-by-cycle current limit function with programmable threshold and a digital output current limit flag, which can be monitored by the host controller. With a fast 25-ns cycle-by-cycle current limit protection, the driver can turn off the power stage in the unlikely event that the digital system cannot respond to a failure situation in time.

9.2 Functional Block Diagram

9.3 Feature Description

9.3.1 Input

The IN pin is a high impedance digital input capable of accepting 3.3-V logic level signals up to 2 MHz. There is an internal Schmitt Trigger comparator which isolates the internal circuitry from any external noise.

If limiting the rise or fall times to the power device is desired, then an external resistance can be added between the output of the driver and the load device, which is generally a power MOSFET gate. The external resistor may also help remove power dissipation from the package.

9.3.2 Current Sensing and Protection

A very fast current limit comparator connected to the CS pin is used to protect the power stage by implementing cycle-by-cycle current limiting.

The current limit threshold is equal to the lesser of the positive inputs at the current limit comparator. The current limit threshold can be set to any value between 0.25 V and 1.0 V by applying the desired threshold voltage to the current limit (ILIM) pin. When the CS level is greater than the ILIM voltage minus 25 mV, the output of the driver is forced low and the current limit flag (CLF) is set high. The CLF signal is latched high until the UCD7K device receives the next rising edge on the IN pin.

When the CS voltage is below ILIM, the driver output will follow the PWM input. The CLF digital output flag can be monitored by the host controller to determine when a current limit event occurs and to then apply the appropriate algorithm to obtain the desired current limit profile.

One of the main benefits of this local protection feature is that the UCD7K devices can protect the power stage if the software code in the digital controller becomes corrupted and hangs up. If the controller's PWM output stays high, the local current sense circuit will turn off the driver output when an over-current condition occurs. The system would likely go into a retry mode because; most DSP and microcontrollers have on-board watchdog, brown-out, and other supervisory peripherals to restart the device in the event that it is not operating properly. But these peripherals typically do not react fast enough to save the power stage. The UCD7K's local current limit comparator provides the required fast protection for the power stage.

The CS threshold is 25 mV below the ILIM voltage. This way, if the user attempts to command zero current ($I_{LIM} < 25 \text{ mV}$) while the CS pin is at ground, for example at start-up, the CLF flag latches high until the IN pin receives a pulse. At start-up it is necessary to ensure that the ILIM pin always greater than the CS pin for the handshaking to work as described below. If for any reason the CS pin comes to within 25 mV of the ILIM pin during start-up, then the CLF flag is latched high and the digital controller must poll the UCD7K device, by sending it a narrow IN pulse. If the fault condition is not present the IN pulse resets the CLF signal to low indicating that the UCD7K device is ready to process power pulses.

9.3.3 Handshaking

The UCD7K family of devices have a built-in handshaking feature to facilitate efficient start-up of the digitally controlled power supply. At start-up the CLF flag is held high until all the internal and external supply voltages of the UCD7K device are within their operating range. Once the supply voltages are within acceptable limits, the CLF goes low and the device will process input drive signals. The micro-controller should monitor the CLF flag at start-up and wait for the CLF flag to go LOW before sending power pulses to the UCD7K device.

9.3.4 Driver Output

The high-current output stage of the UCD7K device family is capable of supplying $\pm 4\text{-A}$ peak current pulses and swings to both VDD and GND. The driver outputs follows the state of the IN pin provided that the VDD and 3V3 voltages are above their respective under-voltage lockout threshold.

The drive output utilizes Texas Instruments' TrueDrive™ architecture, which delivers rated current into the gate of a MOSFET when it is most needed during the Miller plateau region of the switching transition providing efficiency gains.

TrueDrive™ consists of pullup/ pulldown circuits using bipolar and MOSFET transistors in parallel. The peak output current rating is the combined current from the bipolar and MOSFET transistors. The output resistance is the $R_{DS(on)}$ of the MOSFET transistor when the voltage on the driver output is less than the saturation voltage of the bipolar transistor. This hybrid output stage also allows efficient current sourcing at low supply voltages.

Each output stage also provides a very low impedance to overshoot and undershoot due to the body diode of the external MOSFET. This means that in many cases, external-schottky-clamp diodes are not required.

9.3.5 Source/Sink Capabilities During Miller Plateau

Large power MOSFETs present a large load to the control circuitry. Proper drive is required for efficient, reliable operation. The UCD7K drivers have been optimized to provide maximum drive to a power MOSFET during the Miller plateau region of the switching transition. This interval occurs while the drain voltage is swinging between the voltage levels dictated by the power topology, requiring the charging/discharging of the drain-gate capacitance with current supplied or removed by the driver device. See Reference [1]

9.3.6 Drive Current and Power Requirements

The UCD7K family of drivers can deliver high current into a MOSFET gate for a period of several hundred nanoseconds. High peak current is required to turn the device ON quickly. Then, to turn the device OFF, the driver is required to sink a similar amount of current to ground. This repeats at the operating frequency of the power device. A MOSFET is used in this discussion because it is the most common type of switching device used in high frequency power conversion equipment.

Reference [1] discusses the current required to drive a power MOSFET and other capacitive-input switching devices.

When a driver device is tested with a discrete, capacitive load it is a fairly simple matter to calculate the power that is required from the bias supply. The energy that must be transferred from the bias supply to charge the capacitor is given by:

$$E = \frac{1}{2} \times CV^2 \quad (1)$$

where C is the load capacitor and V is the bias voltage feeding the driver.

There is an equal amount of energy transferred to ground when the capacitor is discharged. This leads to a power loss given by the following:

$$P = \frac{1}{2} \times CV^2 \times f \quad (2)$$

where f is the switching frequency.

This power is dissipated in the resistive elements of the circuit. Thus, with no external resistor between the driver and gate, this power is dissipated inside the driver. Half of the total power is dissipated when the capacitor is charged, and the other half is dissipated when the capacitor is discharged. An actual example using the conditions of the previous gate drive waveform should help clarify this.

With $V_{DD} = 12\text{ V}$, $C_{LOAD} = 10\text{ nF}$, and $f = 300\text{ kHz}$, the power loss can be calculated as:

$$P = 10\text{ nF} \times 12^2 \times 300\text{ kHz} = 0.432\text{ W} \quad (3)$$

With a 12-V supply, this would equate to a current of:

$$I = \frac{P}{V} = \frac{0.432\text{ W}}{12\text{ V}} = 0.036\text{ A} \quad (4)$$

The actual current measured from the supply was 0.037 A, and is very close to the predicted value. But, the I_{DD} current that is due to the device internal consumption should be considered. With no load the device current drawn is 0.0027 A. Under this condition the output rise and fall times are faster than with a load. This could lead to an almost insignificant, yet measurable current due to cross-conduction in the output stages of the driver. However, these small current differences are buried in the high frequency switching spikes, and are beyond the measurement capabilities of a basic lab setup. The measured current with 10-nF load is close to the value expected.

The switching load presented by a power MOSFET can be converted to an equivalent capacitance by examining the gate charge required to switch the device. This gate charge includes the effects of the input capacitance plus the added charge needed to swing the drain of the device between the ON and OFF states. Most manufacturers provide specifications that provide the typical and maximum gate charge, in nC, to switch the device under specified conditions. Using the gate charge Q_G , one can determine the power that must be dissipated when charging a capacitor. This is done by using the equivalence $Q_G = C_{EFF} \times V$ to provide the following equation for power:

$$P = C \times V^2 \times f = Q_G \times V \times f \quad (5)$$

This equation allows a power designer to calculate the bias power required to drive a specific MOSFET gate at a specific bias voltage.

Note

The 10% and 90% thresholds depict the dynamics of the bipolar output devices that dominate the power MOSFET transition through the Miller regions of operation.

9.4 Device Functional Modes**9.4.1 Operation with $V_{DD} < 4.25$ V (minimum V_{DD})**

The devices operate with V_{DD} voltages above 4.75 V. The maximum UVLO voltage is 4.75 V, and operates at V_{DD} voltages above 4.75 V. The typical UVLO voltage is 4.5 V. The minimum UVLO voltage is 4.25 V. At V_{DD} below the actual UVLO voltage, the devices do not operate, and OUT remains low.

9.4.2 Operation with IN Pin Open

If the IN pin is disconnected (open), a 100 k Ω internal resistor connects IN to GND to prevent unpredictable operation due to a floating IN pin, and OUT remains low.

9.4.3 Operation with ILIM Pin Open

If the ILIM pin is disconnected (open), the current limit threshold is set at 0.5 V.

9.4.4 Operation with ILIM Pin High

If the signal on ILIM pin is higher than 1 V, the current limit threshold is clamped at 1 V.

10 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

10.1 Application Information

The UCD7100 is part of a family of digital compatible drivers targeting applications utilizing digital control techniques or applications that require local fast peak current limit protection.

10.2 Typical Application

Figure 10-1. Typical Application

10.2.1 Design Requirements

In this design example, the UCD7100 is used to drive a forward converter which is controlled by a digital controller. The switching frequency is 100 KHz, and the input current cycle-by-cycle protection threshold is set at 5 A.

10.2.2 Detailed Design Procedure

The cycle-by-cycle current protection is implemented by connecting the current sense signal to the CS pin. When the CS level is greater than the ILIM voltage minus 25 mV, the output of the driver is forced low and the current limit flag (CLF) is set high. The CLF signal is latched high until the UCD7K device receives the next rising edge on the IN pin.

$$I_{peak} * R_{sense} = V_{ILIM} - 0.025 \quad (6)$$

$$R_{sense} = \frac{V_{ILIM} - 0.025}{I_{peak}} \quad (7)$$

The current limit threshold can be set to any value between 0.25 V and 1.0 V, so R_{sense} must be between 0.045 Ω and 0.195 Ω . For example, if R_{sense} is 0.15 Ω , then V_{ILIM} must be 0.775 V to protect input current at 5 A. If the digital controller has an internal digital-to-analog converter, then it can generate 0.775 V and connect to ILIM directly. For a digital controller without an internal digital-to-analog converter, it can generate a PWM signal, send the PWM signal through a low pass filter, then connect to the ILIM pin. Assuming the magnitude of the PWM pulse is 3.3 V, then the duty cycle is:

$$D = \frac{0.775}{3.3} \quad (8)$$

10.2.3 Application Curve

Figure 10-2. Output Rise and Fall Time ($V_{DD} = 12$ V, $C_{LOAD} = 10$ nF)

11 Power Supply Recommendations

11.1 Supply

The UCD7K devices accept an input range of 4.5 V to 15 V. The device has an internal precision linear regulator that produces the 3V3 output from this VDD input. A separate pin, PVDD, not connected internally to the VDD supply rail provides power for the output drivers. In all applications the same bus voltage supplies the two pins. It is recommended that a low value of resistance be placed between the two pins so that the local capacitance on each pin forms low pass filters to attenuate any switching noise that may be on the bus.

Although quiescent VDD current is low, total supply current will be higher, depending on the gate drive output current required by the switching frequency. Total V_{DD} current is the sum of quiescent V_{DD} current and the average OUT current. Knowing the operating frequency and the MOSFET gate charge (Q_G), average OUT current can be calculated from:

$I_{OUT} = Q_G \times f$, where f is frequency.

For high-speed circuit performance, a V_{DD} bypass capacitor is recommended to prevent noise problems. A 4.7- μ F ceramic capacitor should be located close to the V_{DD} to ground connection. A larger capacitor with relatively low ESR should be connected to the PVDD pin, to help deliver the high current peaks to the load. The capacitors should present a low impedance characteristic for the expected current levels in the driver application. The use of surface mount components for all bypass capacitors is highly recommended.

11.2 Reference and External Bias Supply

All devices in the UCD7K family are capable of supplying a regulated 3.3-V rail to power various types of external loads such as a microcontroller or an ASIC. The onboard linear voltage regulator is capable of sourcing up to 10 mA of current. For normal operation, place a minimum of 0.22 μ F of ceramic capacitance from the reference pin to ground.

12 Layout

12.1 Layout Guidelines

In a power driver operating at high frequency, it is a significant challenge to get clean waveforms without much overshoot/undershoot and ringing. The low output impedance of these drivers produces waveforms with high di/dt . This tends to induce ringing in the parasitic inductances. Utmost care must be used in the circuit layout. It is advantageous to connect the driver IC as close as possible to the leads. The driver device layout has the analog ground on the opposite side of the output, so the ground should be connected to the bypass capacitors and the load with copper trace as wide as possible. These connections should also be made with a small enclosed loop area to minimize the inductance.

12.2 Layout Example

Figure 12-1. Isolated Forward Converter

The useful range of a driver is greatly affected by the drive power requirements of the load and the thermal characteristics of the device package. In order for a power driver to be useful over a particular temperature range the package must allow for the efficient removal of the heat produced while keeping the junction temperature within rated limits. The UCD7K family of drivers is available in PowerPAD™ TSSOP package to cover a range of application requirements. Both have the exposed pads to relieve thermal dissipation from the semiconductor junction.

Note that the PowerPAD™ is not directly connected to any leads of the package. However, it is electrically and thermally connected to the substrate which is the ground of the device.

13 Device and Documentation Support

13.1 Device Support

13.1.1 Development Support

PRODUCT	DESCRIPTION	FEATURES
UCD7201	Dual Low Side ± 4 -A Drivers with Common CS	3V3, CS ⁽¹⁾ (2)
UCD7230	± 4 A Synchronous Buck Driver with CS	3V3, CS ⁽¹⁾ (2)

(1) 3V3 = 3.3V linear regulator.

(2) CS = current sense and current limit function.

13.2 Third-Party Products Disclaimer

TI'S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

13.3 Documentation Support

13.3.1 Related Documentation

1. Texas Instruments, [Power Supply Seminar SEM-1400 Topic 2: Design And Application Guide For High Speed MOSFET Gate Drive Circuits, by Laszlo Balogh](#)
2. Texas Instruments, [Technical Brief, PowerPad Thermally Enhanced Package](#)

All trademarks are the property of their respective owners.

13.7 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

13.8 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

14 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/slma002) and SLMA004 (www.ti.com/lit/slma004).
9. Size of metal pad may vary due to creepage requirement.
10. Vias are optional depending on application, refer to device data sheet. It is recommended that vias under paste be filled, plugged or tented.
