## Keep safety first in your circuit designs!

1. Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage.  
Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

## Notes regarding these materials

1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.
2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein.  
The information described here may contain technical inaccuracies or typographical errors.  
Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.  
Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (<http://www.renesas.com>).
4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.
7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.  
Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

## General Precautions on Handling of Product

### 1. Treatment of NC Pins

**Note:** Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

### 2. Treatment of Unused Input Pins

**Note:** Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

### 3. Processing before Initialization

**Note:** When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

### 4. Prohibition of Access to Undefined or Reserved Addresses

**Note:** Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

# Configuration of This Manual

This manual comprises the following items:

1. General Precautions on Handling of Product
2. Configuration of This Manual
3. Preface
4. Contents
5. Overview
6. Description of Functional Modules

- CPU and System-Control Modules
- On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

7. List of Registers
8. Electrical Characteristics
9. Appendix
10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

# Preface

The H8/3687 Group are single-chip microcomputers made up of the high-speed H8/300H CPU employing Renesas Technology original architecture as their cores, and the peripheral functions required to configure a system. The H8/300H CPU has an instruction set that is compatible with the H8/300 CPU.

**Target Users:** This manual was written for users who will be using the H8/3687 Group in the design of application systems. Target users are expected to understand the fundamentals of electrical circuits, logical circuits, and microcomputers.

**Objective:** This manual was written to explain the hardware functions and electrical characteristics of the H8/3687 Group to the target users.  
Refer to the H8/300H Series Programming Manual for a detailed description of the instruction set.

### Notes on reading this manual:

- In order to understand the overall functions of the chip  
Read the manual according to the contents. This manual can be roughly categorized into parts on the CPU, system control functions, peripheral functions and electrical characteristics.
- In order to understand the details of the CPU's functions  
Read the H8/300H Series Programming Manual.
- In order to understand the details of a register when its name is known  
Read the index that is the final part of the manual to find the page number of the entry on the register. The addresses, bits, and initial values of the registers are summarized in section 22, List of Registers.

Example: Register name: The following notation is used for cases when the same or a similar function, e.g. serial communication interface, is implemented on more than one channel:  
XXX\_N (XXX is the register name and N is the channel number)

Bit order:           The MSB is on the left and the LSB is on the right.

Notes:

When using an on-chip emulator (E10T) for H8/3687 program development and debugging, the following restrictions must be noted (the on-chip debugging emulator (E7) can also be used).

1. The  $\overline{\text{NMI}}$  pin is reserved for the E10T, and cannot be used.

2. Pins P85, P86, and P87 cannot be used. In order to use these pins, additional hardware must be provided on the user board.
3. Area H'D000 to H'DFFF is used by the E10T, and is not available to the user.
4. Area H'F780 to H'FB7F must on no account be accessed.
5. When the E10T is used, address breaks can be set as either available to the user or for use by the E10T. If address breaks are set as being used by the E10T, the address break control registers must not be accessed.
6. When the E10T is used,  $\overline{\text{NMI}}$  is an input/output pin (open-drain in output mode), P85 and P87 are input pins, and P86 is an output pin.

Related Manuals: The latest versions of all related manuals are available from our web site. Please ensure you have the latest versions of all documents you require.

# Section 1 Overview

## 1.1 Features

- High-speed H8/300H central processing unit with an internal 16-bit architecture
  - Upward-compatible with H8/300 CPU on an object level
  - Sixteen 16-bit general registers
  - 62 basic instructions
- Various peripheral functions
  - RTC (can be used as a free running counter)
  - Timer B1 (8-bit timer)
  - Timer V (8-bit timer)
  - Timer Z (16-bit timer)
  - 14-bit PWM
  - Watchdog timer
  - SCI (Asynchronous or clocked synchronous serial communication interface)  $\times 2$  channels
  - I<sup>2</sup>C Bus Interface (conforms to the I<sup>2</sup>C bus interface format that is advocated by Philips Electronics)
  - 10-bit A/D converter

- On-chip memory

| Product Classification                 |                      | Model            |                                                                  | ROM        | RAM       | Remarks  |
|----------------------------------------|----------------------|------------------|------------------------------------------------------------------|------------|-----------|----------|

| EEPROM stacked version (512 bytes)     | Flash memory version | H8/3687N         | —                                                                | HD64N3687G | 56 kbytes | 4 kbytes |
|                                        | Mask-ROM version     | —                | HD6483687G                                                       | 56 kbytes  | 3 kbytes  |          |

- General I/O ports
  - I/O pins: 45 I/O pins (43 I/O pins for H8/3687N), including 8 large current ports ( $I_{OL} = 20$  mA, @  $V_{OL} = 1.5$  V)
  - Input-only pins: 8 input pins (also used for analog input)
- EEPROM interface (only for H8/3687N)
  - I<sup>2</sup>C bus interface (conforms to the I<sup>2</sup>C bus interface format that is advocated by Philips Electronics)
- Supports various power-down states

Note: F-ZTAT™ is a trademark of Renesas Technology Corp.

- Compact package

| Package | Code   | Body Size      | Pin Pitch |
|---------|--------|----------------|-----------|
| LQFP-64 | FP-64E | 10.0 × 10.0 mm | 0.5 mm    |
| QFP-64  | FP-64A | 14.0 × 14.0 mm | 0.8 mm    |

Only LQFP-64 (FP-64E) for H8/3687N package

- Notes: 1. These pins are only available for the I<sup>2</sup>C bus interface in the H8/3687N. Since the I<sup>2</sup>C bus is disabled after canceling a reset, the ICE bit in ICCR1 must be set to 1 by using the program.
2. The P57 and P56 pins are not available in the H8/3687N.

## Section 2 CPU

This LSI has an H8/300H CPU with an internal 32-bit architecture that is upward-compatible with the H8/300CPU, and supports only normal mode, which has a 64-kbyte address space.

- Upward-compatible with H8/300 CPUs
  - Can execute H8/300 CPUs object programs
  - Additional eight 16-bit extended registers
  - 32-bit transfer and arithmetic and logic instructions are added
  - Signed multiply and divide instructions are added.
- General-register architecture
  - Sixteen 16-bit general registers also usable as sixteen 8-bit registers and eight 16-bit registers, or eight 32-bit registers
- Sixty-two basic instructions
  - 8/16/32-bit data transfer and arithmetic and logic instructions
  - Multiply and divide instructions
  - Powerful bit-manipulation instructions
- Eight addressing modes
  - Register direct [Rn]
  - Register indirect [@ERn]
  - Register indirect with displacement [(d:16,ERn) or (d:24,ERn)]
  - Register indirect with post-increment or pre-decrement [@ERn+ or @-ERn]
  - Absolute address [@aa:8, @aa:16, @aa:24]
  - Immediate [#xx:8, #xx:16, or #xx:32]
  - Program-counter relative [(d:8,PC) or (d:16,PC)]
  - Memory indirect [@@aa:8]
- 64-kbyte address space
- High-speed operation
  - All frequently-used instructions execute in one or two states
  - 8/16/32-bit register-register add/subtract : 2 state
  - $8 \times 8$ -bit register-register multiply : 14 states
  - $16 \div 8$ -bit register-register divide : 14 states
  - $16 \times 16$ -bit register-register multiply : 22 states
  - $32 \div 16$ -bit register-register divide : 22 states
- Power-down state
  - Transition to power-down state by SLEEP instruction

## 2.1 Address Space and Memory Map

The address space of this LSI is 64 kbytes, which includes the program area and the data area.

Figures 2.1 show the memory map.

Figure 2.1 Memory Map (1)

**Figure 2.1 Memory Map (2)**

**Figure 2.1 Memory Map (3)**

## 2.2 Register Configuration

The H8/300H CPU has the internal registers shown in figure 2.2. There are two types of registers; general registers and control registers. The control registers are a 24-bit program counter (PC), and an 8-bit condition-code register (CCR).

**Figure 2.2 CPU Registers**

## 2.2.1 General Registers

The H8/300H CPU has eight 32-bit general registers. These general registers are all functionally identical and can be used as both address registers and data registers. When a general register is used as a data register, it can be accessed as a 32-bit, 16-bit, or 8-bit register. Figure 2.3 illustrates the usage of the general registers. When the general registers are used as 32-bit registers or address registers, they are designated by the letters ER (ER0 to ER7).

The ER registers divide into 16-bit general registers designated by the letters E (E0 to E7) and R (R0 to R7). These registers are functionally equivalent, providing a maximum of sixteen 16-bit registers. The E registers (E0 to E7) are also referred to as extended registers.

The R registers divide into 8-bit registers designated by the letters RH (R0H to R7H) and RL (R0L to R7L). These registers are functionally equivalent, providing a maximum of sixteen 8-bit registers.

The usage of each register can be selected independently.

**Figure 2.3 Usage of General Registers**

General register ER7 has the function of stack pointer (SP) in addition to its general-register function, and is used implicitly in exception handling and subroutine calls. Figure 2.4 shows the relationship between the stack pointer and the stack area.

**Figure 2.4 Relationship between Stack Pointer and Stack Area**

### 2.2.2 Program Counter (PC)

This 24-bit counter indicates the address of the next instruction the CPU will execute. The length of all CPU instructions is 2 bytes (one word), so the least significant PC bit is ignored. (When an instruction is fetched, the least significant PC bit is regarded as 0). The PC is initialized when the start address is loaded by the vector address generated during reset exception-handling sequence.

### 2.2.3 Condition-Code Register (CCR)

This 8-bit register contains internal CPU status information, including an interrupt mask bit (I) and half-carry (H), negative (N), zero (Z), overflow (V), and carry (C) flags. The I bit is initialized to 1 by reset exception-handling sequence, but other bits are not initialized.

Some instructions leave flag bits unchanged. Operations can be performed on the CCR bits by the LDC, STC, ANDC, ORC, and XORC instructions. The N, Z, V, and C flags are used as branching conditions for conditional branch (Bcc) instructions.

For the action of each instruction on the flag bits, see appendix A.1, Instruction List.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 0   | C        | Undefined     | R/W | <p>Carry Flag</p> <p>Set to 1 when a carry occurs, and cleared to 0 otherwise. Used by:</p> <ul style="list-style-type: none"> <li>• Add instructions, to indicate a carry</li> <li>• Subtract instructions, to indicate a borrow</li> <li>• Shift and rotate instructions, to indicate a carry</li> </ul> <p>The carry flag is also used as a bit accumulator by bit manipulation instructions.</p>                                                                                                                            |

## 2.3 Data Formats

The H8/300H CPU can process 1-bit, 4-bit (BCD), 8-bit (byte), 16-bit (word), and 32-bit (longword) data. Bit-manipulation instructions operate on 1-bit data by accessing bit  $n$  ( $n = 0, 1, 2, \dots, 7$ ) of byte operand data. The DAA and DAS decimal-adjust instructions treat byte data as two digits of 4-bit BCD data.

### 2.3.1 General Register Data Formats

Figure 2.5 shows the data formats in general registers.

Figure 2.5 General Register Data Formats (1)

**Figure 2.5 General Register Data Formats (2)**

2.3.2 Memory Data Formats

Figure 2.6 shows the data formats in memory. The H8/300H CPU can access word data and longword data in memory, however word or longword data must begin at an even address. If an attempt is made to access word or longword data at an odd address, an address error does not occur, however the least significant bit of the address is regarded as 0, so access begins the preceding address. This also applies to instruction fetches.

When ER7 (SP) is used as an address register to access the stack area, the operand size should be word or longword.

Figure 2.6 Memory Data Formats

## 2.4 Instruction Set

### 2.4.1 Table of Instructions Classified by Function

The H8/300H CPU has 62 instructions. Tables 2.2 to 2.9 summarize the instructions in each functional category. The notation used in tables 2.2 to 2.9 is defined below.

**Table 2.1 Operation Notation**

| Symbol        | Description                                            |
|---------------|--------------------------------------------------------|
| Rd            | General register (destination)*                        |
| Rs            | General register (source)*                             |
| Rn            | General register*                                      |
| ERn           | General register (32-bit register or address register) |
| (EAd)         | Destination operand                                    |
| (EAs)         | Source operand                                         |
| CCR           | Condition-code register                                |
| N             | N (negative) flag in CCR                               |
| Z             | Z (zero) flag in CCR                                   |
| V             | V (overflow) flag in CCR                               |
| C             | C (carry) flag in CCR                                  |
| PC            | Program counter                                        |
| SP            | Stack pointer                                          |
| #IMM          | Immediate data                                         |
| disp          | Displacement                                           |
| +             | Addition                                               |
| −             | Subtraction                                            |
| ×             | Multiplication                                         |
| ÷             | Division                                               |
| ^             | Logical AND                                            |
| ∨             | Logical OR                                             |
| ⊕             | Logical XOR                                            |
| →             | Move                                                   |
| ¬             | NOT (logical complement)                               |
| :3/:8/:16/:24 | 3-, 8-, 16-, or 24-bit length                          |

Note: \* General registers include 8-bit registers (R0H to R7H, R0L to R7L), 16-bit registers (R0 to R7, E0 to E7), and 32-bit registers/address register (ER0 to ER7).

**Table 2.2 Data Transfer Instructions**

| Instruction | Size* | Function                                                                                                                                                    |
|-------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MOV         | B/W/L | (EAs) → Rd, Rs → (EAd)<br>Moves data between two general registers or between a general register and memory, or moves immediate data to a general register. |
| MOVFPE      | B     | (EAs) → Rd<br>Cannot be used in this LSI.                                                                                                                   |
| MOVTPE      | B     | Rs → (EAs)<br>Cannot be used in this LSI.                                                                                                                   |
| POP         | W/L   | @SP+ → Rn<br>Pops a general register from the stack. POP.W Rn is identical to MOV.W @SP+, Rn. POP.L ERn is identical to MOV.L @SP+, ERn.                    |
| PUSH        | W/L   | Rn → @-SP<br>Pushes a general register onto the stack. PUSH.W Rn is identical to MOV.W Rn, @-SP. PUSH.L ERn is identical to MOV.L ERn, @-SP.                |

Note: \* Refers to the operand size.

L: Longword

**Table 2.6 Bit Manipulation Instructions (1)**

| Instruction | Size* | Function                                                                                                                                                                                                                                                        |
|-------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BSET        | B     | $1 \rightarrow (\text{<bit-No.> of <EAd>})$<br>Sets a specified bit in a general register or memory operand to 1. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.                                            |
| BCLR        | B     | $0 \rightarrow (\text{<bit-No.> of <EAd>})$<br>Clears a specified bit in a general register or memory operand to 0. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.                                          |
| BNOT        | B     | $\neg (\text{<bit-No.> of <EAd>}) \rightarrow (\text{<bit-No.> of <EAd>})$<br>Inverts a specified bit in a general register or memory operand. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.               |
| BTST        | B     | $\neg (\text{<bit-No.> of <EAd>}) \rightarrow Z$<br>Tests a specified bit in a general register or memory operand and sets or clears the Z flag accordingly. The bit number is specified by 3-bit immediate data or the lower three bits of a general register. |
| BAND        | B     | $C \wedge (\text{<bit-No.> of <EAd>}) \rightarrow C$<br>ANDs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.                                                                               |
| BIAND       | B     | $C \wedge \neg (\text{<bit-No.> of <EAd>}) \rightarrow C$<br>ANDs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.      |
| BOR         | B     | $C \vee (\text{<bit-No.> of <EAd>}) \rightarrow C$<br>ORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.                                                                                  |
| BIOR        | B     | $C \vee \neg (\text{<bit-No.> of <EAd>}) \rightarrow C$<br>ORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.         |

Note: \* Refers to the operand size.

B: Byte

**Table 2.6 Bit Manipulation Instructions (2)**

| Instruction | Size* | Function                                                                                                                                                                                                                                                                                                |
|-------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BXOR        | B     | $C \oplus \langle \text{bit-No.} \rangle \text{ of } \langle \text{EAd} \rangle \rightarrow C$<br>XORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.                                                                             |
| BIXOR       | B     | $C \oplus \neg \langle \text{bit-No.} \rangle \text{ of } \langle \text{EAd} \rangle \rightarrow C$<br>XORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag.<br>The bit number is specified by 3-bit immediate data. |
| BLD         | B     | $\langle \text{bit-No.} \rangle \text{ of } \langle \text{EAd} \rangle \rightarrow C$<br>Transfers a specified bit in a general register or memory operand to the carry flag.                                                                                                                           |
| BILD        | B     | $\neg \langle \text{bit-No.} \rangle \text{ of } \langle \text{EAd} \rangle \rightarrow C$<br>Transfers the inverse of a specified bit in a general register or memory operand to the carry flag.<br>The bit number is specified by 3-bit immediate data.                                               |
| BST         | B     | $C \rightarrow \langle \text{bit-No.} \rangle \text{ of } \langle \text{EAd} \rangle$<br>Transfers the carry flag value to a specified bit in a general register or memory operand.                                                                                                                     |
| BIST        | B     | $\neg C \rightarrow \langle \text{bit-No.} \rangle \text{ of } \langle \text{EAd} \rangle$<br>Transfers the inverse of the carry flag value to a specified bit in a general register or memory operand.<br>The bit number is specified by 3-bit immediate data.                                         |

Note: \* Refers to the operand size.

B: Byte

**Table 2.7 Branch Instructions**

| Instruction | Size                          | Function                                                                                                     |
|-------------|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| Bcc*        | —                             | Branches to a specified address if a specified condition is true. The branching conditions are listed below. |
| Mnemonic    | Description                   | Condition                                                                                                    |
| BRA(BT)     | Always (true)                 | Always                                                                                                       |
| BRN(BF)     | Never (false)                 | Never                                                                                                        |
| BHI         | High                          | $C \vee Z = 0$                                                                                               |
| BLS         | Low or same                   | $C \vee Z = 1$                                                                                               |
| BCC(BHS)    | Carry clear<br>(high or same) | $C = 0$                                                                                                      |
| BCS(BLO)    | Carry set (low)               | $C = 1$                                                                                                      |
| BNE         | Not equal                     | $Z = 0$                                                                                                      |
| BEQ         | Equal                         | $Z = 1$                                                                                                      |
| BVC         | Overflow clear                | $V = 0$                                                                                                      |
| BVS         | Overflow set                  | $V = 1$                                                                                                      |
| BPL         | Plus                          | $N = 0$                                                                                                      |
| BMI         | Minus                         | $N = 1$                                                                                                      |
| BGE         | Greater or equal              | $N \oplus V = 0$                                                                                             |
| BLT         | Less than                     | $N \oplus V = 1$                                                                                             |
| BGT         | Greater than                  | $Z \vee (N \oplus V) = 0$                                                                                    |
| BLE         | Less or equal                 | $Z \vee (N \oplus V) = 1$                                                                                    |
| JMP         | —                             | Branches unconditionally to a specified address.                                                             |
| BSR         | —                             | Branches to a subroutine at a specified address.                                                             |
| JSR         | —                             | Branches to a subroutine at a specified address.                                                             |
| RTS         | —                             | Returns from a subroutine                                                                                    |

Note: \* Bcc is the general name for conditional branch instructions.

**Table 2.8 System Control Instructions**

| Instruction | Size* | Function                                                                                                                                                                      |
|-------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRAPA       | —     | Starts trap-instruction exception handling.                                                                                                                                   |
| RTE         | —     | Returns from an exception-handling routine.                                                                                                                                   |
| SLEEP       | —     | Causes a transition to a power-down state.                                                                                                                                    |
| LDC         | B/W   | (EAs) → CCR<br>Moves the source operand contents to the CCR. The CCR size is one byte, but in transfer from memory, data is read by word access.                              |
| STC         | B/W   | CCR → (EAd)<br>Transfers the CCR contents to a destination location. The condition code register size is one byte, but in transfer to memory, data is written by word access. |
| ANDC        | B     | CCR ∧ #IMM → CCR<br>Logically ANDs the CCR with immediate data.                                                                                                               |
| ORC         | B     | CCR ∨ #IMM → CCR<br>Logically ORs the CCR with immediate data.                                                                                                                |
| XORC        | B     | CCR ⊕ #IMM → CCR<br>Logically XORs the CCR with immediate data.                                                                                                               |
| NOP         | —     | PC + 2 → PC<br>Only increments the program counter.                                                                                                                           |

Note: \* Refers to the operand size.

B: Byte

W: Word

**Table 2.9 Block Data Transfer Instructions**

| Instruction | Size | Function                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EEPMOV.B    | —    | <p>if R4L <math>\neq</math> 0 then<br/>Repeat @ER5+ <math>\rightarrow</math> @ER6+,<br/>R4L-1 <math>\rightarrow</math> R4L<br/>Until R4L = 0<br/>else next;</p>                                                                                                                                                                                                                                                    |
| EEPMOV.W    | —    | <p>if R4 <math>\neq</math> 0 then<br/>Repeat @ER5+ <math>\rightarrow</math> @ER6+,<br/>R4-1 <math>\rightarrow</math> R4<br/>Until R4 = 0<br/>else next;</p> <p>Transfers a data block. Starting from the address set in ER5, transfers data for the number of bytes set in R4L or R4 to the address location set in ER6.</p> <p>Execution of the next instruction begins as soon as the transfer is completed.</p> |

## 2.4.2 Basic Instruction Formats

H8/300H CPU instructions consist of 2-byte (1-word) units. An instruction consists of an operation field (op), a register field (r), an effective address extension (EA), and a condition field (cc).

Figure 2.7 shows examples of instruction formats.

- **Operation Field**  
Indicates the function of the instruction, the addressing mode, and the operation to be carried out on the operand. The operation field always includes the first four bits of the instruction. Some instructions have two operation fields.
- **Register Field**  
Specifies a general register. Address registers are specified by 3 bits, and data registers by 3 bits or 4 bits. Some instructions have two register fields. Some have no register field.
- **Effective Address Extension**  
8, 16, or 32 bits specifying immediate data, an absolute address, or a displacement. A 24-bit address or displacement is treated as a 32-bit data in which the first 8 bits are 0 (H'00).
- **Condition Field**  
Specifies the branching condition of Bcc instructions.

**Figure 2.7 Instruction Formats**

## 2.5 Addressing Modes and Effective Address Calculation

The following describes the H8/300H CPU. In this LSI, the upper eight bits are ignored in the generated 24-bit address, so the effective address is 16 bits.

### 2.5.1 Addressing Modes

The H8/300H CPU supports the eight addressing modes listed in table 2.10. Each instruction uses a subset of these addressing modes. Addressing modes that can be used differ depending on the instruction. For details, refer to appendix A.4, Combinations of Instructions and Addressing Modes.

Arithmetic and logic instructions can use the register direct and immediate modes. Data transfer instructions can use all addressing modes except program-counter relative and memory indirect. Bit-manipulation instructions use register direct, register indirect, or the absolute addressing mode (@aa:8) to specify an operand, and register direct (BSET, BCLR, BNOT, and BTST instructions) or immediate (3-bit) addressing mode to specify a bit number in the operand.

**Table 2.10 Addressing Modes**

| No. | Addressing Mode                                                               | Symbol                  |
|-----|-------------------------------------------------------------------------------|-------------------------|
| 1   | Register direct                                                               | Rn                      |
| 2   | Register indirect                                                             | @ERn                    |
| 3   | Register indirect with displacement                                           | @(d:16,ERn)/@(d:24,ERn) |
| 4   | Register indirect with post-increment<br>Register indirect with pre-decrement | @ERn+<br>@-ERn          |
| 5   | Absolute address                                                              | @aa:8/@aa:16/@aa:24     |
| 6   | Immediate                                                                     | #xx:8/#xx:16/#xx:32     |
| 7   | Program-counter relative                                                      | @(d:8,PC)/@(d:16,PC)    |
| 8   | Memory indirect                                                               | @ @aa:8                 |

#### Register Direct—Rn

The register field of the instruction specifies an 8-, 16-, or 32-bit general register containing the operand. R0H to R7H and R0L to R7L can be specified as 8-bit registers. R0 to R7 and E0 to E7 can be specified as 16-bit registers. ER0 to ER7 can be specified as 32-bit registers.

#### Register Indirect—@ERn

The register field of the instruction code specifies an address register (ERn), the lower 24 bits of which contain the address of the operand on memory.

### Register Indirect with Displacement—@(**d:16, ERn**) or @(**d:24, ERn**)

A 16-bit or 24-bit displacement contained in the instruction is added to an address register (ERn) specified by the register field of the instruction, and the lower 24 bits of the sum the address of a memory operand. A 16-bit displacement is sign-extended when added.

### Register Indirect with Post-Increment or Pre-Decrement—@ERn+ or @-ERn

- Register indirect with post-increment—@ERn+  
The register field of the instruction code specifies an address register (ERn) the lower 24 bits of which contains the address of a memory operand. After the operand is accessed, 1, 2, or 4 is added to the address register contents (32 bits) and the sum is stored in the address register. The value added is 1 for byte access, 2 for word access, or 4 for longword access. For the word or longword access, the register value should be even.
- Register indirect with pre-decrement—@-ERn  
The value 1, 2, or 4 is subtracted from an address register (ERn) specified by the register field in the instruction code, and the lower 24 bits of the result is the address of a memory operand. The result is also stored in the address register. The value subtracted is 1 for byte access, 2 for word access, or 4 for longword access. For the word or longword access, the register value should be even.

### Absolute Address—@aa:8, @aa:16, @aa:24

The instruction code contains the absolute address of a memory operand. The absolute address may be 8 bits long (@aa:8), 16 bits long (@aa:16), 24 bits long (@aa:24)

For an 8-bit absolute address, the upper 16 bits are all assumed to be 1 (H'FFFF). For a 16-bit absolute address the upper 8 bits are a sign extension. A 24-bit absolute address can access the entire address space.

The access ranges of absolute addresses for the group of this LSI are those shown in table 2.11, because the upper 8 bits are ignored.

**Table 2.11 Absolute Address Access Ranges**

| Absolute Address | Access Range     |
|------------------|------------------|
| 8 bits (@aa:8)   | H'FF00 to H'FFFF |
| 16 bits (@aa:16) | H'0000 to H'FFFF |
| 24 bits (@aa:24) | H'0000 to H'FFFF |

### Immediate—#xx:8, #xx:16, or #xx:32

The instruction contains 8-bit (#xx:8), 16-bit (#xx:16), or 32-bit (#xx:32) immediate data as an operand.

The ADDS, SUBS, INC, and DEC instructions contain immediate data implicitly. Some bit manipulation instructions contain 3-bit immediate data in the instruction code, specifying a bit number. The TRAPA instruction contains 2-bit immediate data in its instruction code, specifying a vector address.

### Program-Counter Relative—@(d:8, PC) or @(d:16, PC)

This mode is used in the BSR instruction. An 8-bit or 16-bit displacement contained in the instruction is sign-extended and added to the 24-bit PC contents to generate a branch address. The PC value to which the displacement is added is the address of the first byte of the next instruction, so the possible branching range is –126 to +128 bytes (–63 to +64 words) or –32766 to +32768 bytes (–16383 to +16384 words) from the branch instruction. The resulting value should be an even number.

### Memory Indirect—@@aa:8

This mode can be used by the JMP and JSR instructions. The instruction code contains an 8-bit absolute address specifying a memory operand. This memory operand contains a branch address. The memory operand is accessed by longword access. The first byte of the memory operand is ignored, generating a 24-bit branch address. Figure 2.8 shows how to specify branch address for in memory indirect mode. The upper bits of the absolute address are all assumed to be 0, so the address range is 0 to 255 (H'0000 to H'00FF).

Note that the first part of the address range is also the exception vector area.

**Figure 2.8 Branch Address Specification in Memory Indirect Mode**

## 2.5.2 Effective Address Calculation

Table 2.12 indicates how effective addresses are calculated in each addressing mode. In this LSI the upper 8 bits of the effective address are ignored in order to generate a 16-bit effective address.

**Table 2.12 Effective Address Calculation (1)**

| No | Addressing Mode and Instruction Format                                                                                                                                                                                                                              | Effective Address Calculation                                                                                                                                  | Effective Address (EA)                                                                                  |

## 2.6 Basic Bus Cycle

CPU operation is synchronized by a system clock ( $\phi$ ) or a subclock ( $\phi_{\text{SUB}}$ ). The period from a rising edge of  $\phi$  or  $\phi_{\text{SUB}}$  to the next rising edge is called one state. A bus cycle consists of two states or three states. The cycle differs depending on whether access is to on-chip memory or to on-chip peripheral modules.

### 2.6.1 Access to On-Chip Memory (RAM, ROM)

Access to on-chip memory takes place in two states. The data bus width is 16 bits, allowing access in byte or word size. Figure 2.9 shows the on-chip memory access cycle.

**Figure 2.9 On-Chip Memory Access Cycle**

## 2.6.2 On-Chip Peripheral Modules

On-chip peripheral modules are accessed in two states or three states. The data bus width is 8 bits or 16 bits depending on the register. For description on the data bus width and number of accessing states of each register, refer to section 22.1, Register Addresses (Address Order). Registers with 16-bit data bus width can be accessed by word size only. Registers with 8-bit data bus width can be accessed by byte or word size. When a register with 8-bit data bus width is accessed by word size, a bus cycle occurs twice. In two-state access, the operation timing is the same as that for on-chip memory.

Figure 2.10 shows the operation timing in the case of three-state access to an on-chip peripheral module.

**Figure 2.10 On-Chip Peripheral Module Access Cycle (3-State Access)**

## 2.7 CPU States

There are four CPU states: the reset state, program execution state, program halt state, and exception-handling state. The program execution state includes active mode and subactive mode. For the program halt state, there are a sleep mode, standby mode, and sub-sleep mode. These states are shown in figure 2.11. Figure 2.12 shows the state transitions. For details on program execution state and program halt state, refer to section 6, Power-Down Modes. For details on exception processing, refer to section 3, Exception Handling.

**Figure 2.11 CPU Operation States**

**Figure 2.12 State Transitions**

## 2.8 Usage Notes

### 2.8.1 Notes on Data Access to Empty Areas

The address space of this LSI includes empty areas in addition to the ROM, RAM, and on-chip I/O registers areas available to the user. When data is transferred from CPU to empty areas, the transferred data will be lost. This action may also cause the CPU to malfunction. When data is transferred from an empty area to CPU, the contents of the data cannot be guaranteed.

### 2.8.2 EEPMOV Instruction

EEPMOV is a block-transfer instruction and transfers the byte size of data indicated by R4L, which starts from the address indicated by R5, to the address indicated by R6. Set R4L and R6 so that the end address of the destination address (value of  $R6 + R4L$ ) does not exceed H'FFFF (the value of R6 must not change from H'FFFF to H'0000 during execution).

### 2.8.3 Bit-Manipulation Instruction

The BSET, BCLR, BNOT, BST, and BIST instructions read data from the specified address in byte units, manipulate the data of the target bit, and write data to the same address again in byte units. Special care is required when using these instructions in cases where two registers are assigned to the same address, or when a bit is directly manipulated for a port or a register containing a write-only bit, because this may rewrite data of a bit other than the bit to be manipulated.

## Bit manipulation for two registers assigned to the same address

### Example 1: Bit manipulation for the timer load register and timer counter

(Applicable for timer B1 in the H8/3687 Group.)

Figure 2.13 shows an example of a timer in which two timer registers are assigned to the same address. When a bit-manipulation instruction accesses the timer load register and timer counter of a reloadable timer, since these two registers share the same address, the following operations takes place.

1. Data is read in byte units.
2. The CPU sets or resets the bit to be manipulated with the bit-manipulation instruction.
3. The written data is written again in byte units to the timer load register.

The timer is counting, so the value read is not necessarily the same as the value in the timer load register. As a result, bits other than the intended bit in the timer counter may be modified and the modified value may be written to the timer load register.

**Figure 2.13 Example of Timer Configuration with Two Registers Allocated to Same Address**

### Example 2: The BSET instruction is executed for port 5.

P57 and P56 are input pins, with a low-level signal input at P57 and a high-level signal input at P56. P55 to P50 are output pins and output low-level signals. An example to output a high-level signal at P50 with a BSET instruction is shown below.

- Prior to executing BSET instruction

|              | P57       | P56        | P55       | P54       | P53       | P52       | P51       | P50       |
|--------------|-----------|------------|-----------|-----------|-----------|-----------|-----------|-----------|
| Input/output | Input     | Input      | Output    | Output    | Output    | Output    | Output    | Output    |
| Pin state    | Low level | High level | Low level | Low level | Low level | Low level | Low level | Low level |
| PCR5         | 0         | 0          | 1         | 1         | 1         | 1         | 1         | 1         |
| PDR5         | 1         | 0          | 0         | 0         | 0         | 0         | 0         | 0         |

- BSET instruction executed instruction

```
BSET    #0,    @PDR5
```

The BSET instruction is executed for port 5.

- After executing BSET instruction

|              | P57       | P56        | P55       | P54       | P53       | P52       | P51       | P50        |
|--------------|-----------|------------|-----------|-----------|-----------|-----------|-----------|------------|
| Input/output | Input     | Input      | Output    | Output    | Output    | Output    | Output    | Output     |
| Pin state    | Low level | High level | Low level | Low level | Low level | Low level | Low level | High level |
| PCR5         | 0         | 0          | 1         | 1         | 1         | 1         | 1         | 1          |
| PDR5         | 0         | 1          | 0         | 0         | 0         | 0         | 0         | 1          |

- Description on operation

1. When the BSET instruction is executed, first the CPU reads port 5.

Since P57 and P56 are input pins, the CPU reads the pin states (low-level and high-level input).

P55 to P50 are output pins, so the CPU reads the value in PDR5. In this example PDR5 has a value of H'80, but the value read by the CPU is H'40.

2. Next, the CPU sets bit 0 of the read data to 1, changing the PDR5 data to H'41.
3. Finally, the CPU writes H'41 to PDR5, completing execution of BSET instruction.

As a result of the BSET instruction, bit 0 in PDR5 becomes 1, and P50 outputs a high-level signal. However, bits 7 and 6 of PDR5 end up with different values. To prevent this problem, store a copy of the PDR5 data in a work area in memory. Perform the bit manipulation on the data in the work area, then write this data to PDR5.

- Prior to executing BSET instruction

```
MOV.B    #80,    R0L
MOV.B    R0L,    @RAM0
MOV.B    R0L,    @PDR5
```

The PDR5 value (H'80) is written to a work area in memory (RAM0) as well as to PDR5.

|              | P57       | P56        | P55       | P54       | P53       | P52       | P51       | P50       |
|--------------|-----------|------------|-----------|-----------|-----------|-----------|-----------|-----------|
| Input/output | Input     | Input      | Output    | Output    | Output    | Output    | Output    | Output    |
| Pin state    | Low level | High level | Low level | Low level | Low level | Low level | Low level | Low level |
| PCR5         | 0         | 0          | 1         | 1         | 1         | 1         | 1         | 1         |
| PDR5         | 1         | 0          | 0         | 0         | 0         | 0         | 0         | 0         |

- BSET instruction executed

```
BSET     #0,      @RAM0
```

The BSET instruction is executed designating the PDR5 work area (RAM0).

- After executing BSET instruction

```
MOV.B    @RAM0,   R0L
MOV.B    R0L,     @PDR5
```

The work area (RAM0) value is written to PDR5.

## Bit Manipulation in a Register Containing a Write-Only Bit

### Example 3: BCLR instruction executed designating port 5 control register PCR5

P57 and P56 are input pins, with a low-level signal input at P57 and a high-level signal input at P56. P55 to P50 are output pins that output low-level signals. An example of setting the P50 pin as an input pin by the BCLR instruction is shown below. It is assumed that a high-level signal will be input to this input pin.

- Prior to executing BCLR instruction

|              | P57       | P56        | P55       | P54       | P53       | P52       | P51       | P50       |
|--------------|-----------|------------|-----------|-----------|-----------|-----------|-----------|-----------|
| Input/output | Input     | Input      | Output    | Output    | Output    | Output    | Output    | Output    |

| PCR5         | 0         | 0          | 1         | 1         | 1         | 1         | 1         | 1         |
| PDR5         | 1         | 0          | 0         | 0         | 0         | 0         | 0         | 0         |

- BCLR instruction executed

BCLR #0, @PCR5

The BCLR instruction is executed for PCR5.

- After executing BCLR instruction

|              | P57       | P56        | P55       | P54       | P53       | P52       | P51       | P50        |
|--------------|-----------|------------|-----------|-----------|-----------|-----------|-----------|------------|
| Input/output | Output    | Output     | Output    | Output    | Output    | Output    | Output    | Input      |
| Pin state    | Low level | High level | Low level | Low level | Low level | Low level | Low level | High level |
| PCR5         | 1         | 1          | 1         | 1         | 1         | 1         | 1         | 0          |
| PDR5         | 1         | 0          | 0         | 0         | 0         | 0         | 0         | 0          |

- Description on operation

1. When the BCLR instruction is executed, first the CPU reads PCR5. Since PCR5 is a write-only register, the CPU reads a value of H'FF, even though the PCR5 value is actually H'3F.
2. Next, the CPU clears bit 0 in the read data to 0, changing the data to H'FE.
3. Finally, H'FE is written to PCR5 and BCLR instruction execution ends.

As a result of this operation, bit 0 in PCR5 becomes 0, making P50 an input port. However, bits 7 and 6 in PCR5 change to 1, so that P57 and P56 change from input pins to output pins. To prevent this problem, store a copy of the PDR5 data in a work area in memory and manipulate data of the bit in the work area, then write this data to PDR5.

- Prior to executing BCLR instruction

```
MOV.B    #3F,    R0L
MOV.B    R0L,    @RAM0
MOV.B    R0L,    @PCR5
```

The PCR5 value (H'3F) is written to a work area in memory (RAM0) as well as to PCR5.

|              | P57       | P56        | P55       | P54       | P53       | P52       | P51       | P50       |
|--------------|-----------|------------|-----------|-----------|-----------|-----------|-----------|-----------|

| PCR5         | 0         | 0          | 1         | 1         | 1         | 1         | 1         | 1         |
| PDR5         | 1         | 0          | 0         | 0         | 0         | 0         | 0         | 0         |
| RAM0         | 0         | 0          | 1         | 1         | 1         | 1         | 1         | 1         |

- BCLR instruction executed

```
BCLR    #0,    @RAM0
```

The BCLR instructions executed for the PCR5 work area (RAM0).

- After executing BCLR instruction

```
MOV.B    @RAM0, R0L
MOV.B    R0L,    @PCR5
```

The work area (RAM0) value is written to PCR5.

## Section 3 Exception Handling

Exception handling may be caused by a reset, a trap instruction (TRAPA), or interrupts.

- Reset

A reset has the highest exception priority. Exception handling starts as soon as the reset is cleared by the  $\overline{\text{RES}}$  pin. The chip is also reset when the watchdog timer overflows, and exception handling starts. Exception handling is the same as exception handling by the  $\overline{\text{RES}}$  pin.

- Trap Instruction

Exception handling starts when a trap instruction (TRAPA) is executed. The TRAPA instruction generates a vector address corresponding to a vector number from 0 to 3, as specified in the instruction code. Exception handling can be executed at all times in the program execution state, regardless of the setting of the I bit in CCR.

- Interrupts

External interrupts other than NMI and internal interrupts other than address break are masked by the I bit in CCR, and kept masked while the I bit is set to 1. Exception handling starts when the current instruction or exception handling ends, if an interrupt request has been issued.

### 3.1 Exception Sources and Vector Address

Table 3.1 shows the vector addresses and priority of each exception handling. When more than one interrupt is requested, handling is performed from the interrupt with the highest priority.

**Table 3.1 Exception Sources and Vector Address**

| Relative Module            | Exception Sources                                                                                                                        | Vector Number | Vector Address   | Priority                                   |

### 3.2.1 Interrupt Edge Select Register 1 (IEGR1)

IEGR1 selects the direction of an edge that generates interrupt requests of pins  $\overline{\text{NMI}}$  and  $\overline{\text{IRQ3}}$  to  $\overline{\text{IRQ0}}$ .

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                               |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | NMIEG    | 0             | R/W | NMI Edge Select<br>0: Falling edge of $\overline{\text{NMI}}$ pin input is detected<br>1: Rising edge of $\overline{\text{NMI}}$ pin input is detected    |
| 6 to 4 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                              |
| 3      | IEG3     | 0             | R/W | IRQ3 Edge Select<br>0: Falling edge of $\overline{\text{IRQ3}}$ pin input is detected<br>1: Rising edge of $\overline{\text{IRQ3}}$ pin input is detected |
| 2      | IEG2     | 0             | R/W | IRQ2 Edge Select<br>0: Falling edge of $\overline{\text{IRQ2}}$ pin input is detected<br>1: Rising edge of $\overline{\text{IRQ2}}$ pin input is detected |
| 1      | IEG1     | 0             | R/W | IRQ1 Edge Select<br>0: Falling edge of $\overline{\text{IRQ1}}$ pin input is detected<br>1: Rising edge of $\overline{\text{IRQ1}}$ pin input is detected |
| 0      | IEG0     | 0             | R/W | IRQ0 Edge Select<br>0: Falling edge of $\overline{\text{IRQ0}}$ pin input is detected<br>1: Rising edge of $\overline{\text{IRQ0}}$ pin input is detected |

### 3.2.2 Interrupt Edge Select Register 2 (IEGR2)

IEGR2 selects the direction of an edge that generates interrupt requests of the pins  $\overline{\text{ADTRG}}$  and  $\overline{\text{WKP5}}$  to  $\overline{\text{WKP0}}$ .

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                 |
|------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7, 6 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                                |
| 5    | WPEG5    | 0             | R/W | WKP5 Edge Select<br>0: Falling edge of $\overline{\text{WKP5}}(\overline{\text{ADTRG}})$ pin input is detected<br>1: Rising edge of $\overline{\text{WKP5}}(\overline{\text{ADTRG}})$ pin input is detected |
| 4    | WPEG4    | 0             | R/W | WKP4 Edge Select<br>0: Falling edge of $\overline{\text{WKP4}}$ pin input is detected<br>1: Rising edge of $\overline{\text{WKP4}}$ pin input is detected                                                   |
| 3    | WPEG3    | 0             | R/W | WKP3 Edge Select<br>0: Falling edge of $\overline{\text{WKP3}}$ pin input is detected<br>1: Rising edge of $\overline{\text{WKP3}}$ pin input is detected                                                   |
| 2    | WPEG2    | 0             | R/W | WKP2 Edge Select<br>0: Falling edge of $\overline{\text{WKP2}}$ pin input is detected<br>1: Rising edge of $\overline{\text{WKP2}}$ pin input is detected                                                   |
| 1    | WPEG1    | 0             | R/W | WKP1 Edge Select<br>0: Falling edge of $\overline{\text{WKP1}}$ pin input is detected<br>1: Rising edge of $\overline{\text{WKP1}}$ pin input is detected                                                   |
| 0    | WPEG0    | 0             | R/W | WKP0 Edge Select<br>0: Falling edge of $\overline{\text{WKP0}}$ pin input is detected<br>1: Rising edge of $\overline{\text{WKP0}}$ pin input is detected                                                   |

### 3.2.3 Interrupt Enable Register 1 (IENR1)

IENR1 enables direct transition interrupts, RTC interrupts, and external pin interrupts.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                          |
|-----|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | IENDT    | 0             | R/W | Direct Transfer Interrupt Enable<br>When this bit is set to 1, direct transition interrupt requests are enabled.                                                                     |
| 6   | IENTA    | 0             | R/W | RTC Interrupt Enable<br>When this bit is set to 1, RTC interrupt requests are enabled.                                                                                               |
| 5   | IENWP    | 0             | R/W | Wakeup Interrupt Enable<br>This bit is an enable bit, which is common to the pins $\overline{WKP5}$ to $\overline{WKP0}$ . When the bit is set to 1, interrupt requests are enabled. |
| 4   | —        | 1             | —   | Reserved<br>This bit is always read as 1.                                                                                                                                            |
| 3   | IEN3     | 0             | R/W | IRQ3 Interrupt Enable<br>When this bit is set to 1, interrupt requests of the $\overline{IRQ3}$ pin are enabled.                                                                     |
| 2   | IEN2     | 0             | R/W | IRQ2 Interrupt Enable<br>When this bit is set to 1, interrupt requests of the $\overline{IRQ2}$ pin are enabled.                                                                     |
| 1   | IEN1     | 0             | R/W | IRQ1 Interrupt Enable<br>When this bit is set to 1, interrupt requests of the $\overline{IRQ1}$ pin are enabled.                                                                     |
| 0   | IEN0     | 0             | R/W | IRQ0 Interrupt Enable<br>When this bit is set to 1, interrupt requests of the $\overline{IRQ0}$ pin are enabled.                                                                     |

When disabling interrupts by clearing bits in an interrupt enable register, or when clearing bits in an interrupt flag register, always do so while interrupts are masked ( $I = 1$ ). If the above clear operations are performed while  $I = 0$ , and as a result a conflict arises between the clear instruction and an interrupt request, exception handling for the interrupt will be executed after the clear instruction has been executed.

### 3.2.4 Interrupt Enable Register 2 (IENR2)

IENR2 enables, timer B1 overflow interrupts.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                               |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------|
| 7, 6   | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                                              |
| 5      | IENRB1   | 0             | R/W | Timer B1 Interrupt Enable<br>When this bit is set to 1, timer B1 overflow interrupt requests are enabled. |
| 4 to 0 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                              |

When disabling interrupts by clearing bits in an interrupt enable register, or when clearing bits in an interrupt flag register, always do so while interrupts are masked ( $I = 1$ ). If the above clear operations are performed while  $I = 0$ , and as a result a conflict arises between the clear instruction and an interrupt request, exception handling for the interrupt will be executed after the clear instruction has been executed.

### 3.2.5 Interrupt Flag Register 1 (IRR1)

IRR1 is a status flag register for direct transition interrupts, RTC interrupts, and  $\overline{IRQ3}$  to  $\overline{IRQ0}$  interrupt requests.

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                      |
|------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | IRRDT    | 0             | R/W | Direct Transfer Interrupt Request Flag<br>[Setting condition]<br>When a direct transfer is made by executing a SLEEP instruction while DTON in SYSCR2 is set to 1.<br>[Clearing condition]<br>When IRRDT is cleared by writing 0 |
| 6    | IRRRTA   | 0             | R/W | RTC Interrupt Request Flag<br>[Setting condition]<br>When the RTC counter value overflows<br>[Clearing condition]<br>When IRRRTA is cleared by writing 0                                                                         |
| 5, 4 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                                                     |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                         |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | IRRI3    | 0             | R/W | IRQ3 Interrupt Request Flag<br>[Setting condition]<br>When $\overline{\text{IRQ3}}$ pin is designated for interrupt input and the designated signal edge is detected.<br>[Clearing condition]<br>When IRRI3 is cleared by writing 0 |
| 2   | IRRI2    | 0             | R/W | IRQ2 Interrupt Request Flag<br>[Setting condition]<br>When $\overline{\text{IRQ2}}$ pin is designated for interrupt input and the designated signal edge is detected.<br>[Clearing condition]<br>When IRRI2 is cleared by writing 0 |
| 1   | IRRI1    | 0             | R/W | IRQ1 Interrupt Request Flag<br>[Setting condition]<br>When $\overline{\text{IRQ1}}$ pin is designated for interrupt input and the designated signal edge is detected.<br>[Clearing condition]<br>When IRRI1 is cleared by writing 0 |
| 0   | IRRI0    | 0             | R/W | IRQ0 Interrupt Request Flag<br>[Setting condition]<br>When $\overline{\text{IRQ0}}$ pin is designated for interrupt input and the designated signal edge is detected.<br>[Clearing condition]<br>When IRRIO is cleared by writing 0 |

### 3.2.6 Interrupt Flag Register 2 (IRR2)

IRR2 is a status flag register for timer B1 overflow interrupts.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                        |
|--------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7, 6   | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                                                                                                       |
| 5      | IRRTB1   | 0             | R/W | Timer B1 Interrupt Request flag<br>[Setting condition]<br>When the timer B1 counter value overflows<br>[Clearing condition]<br>When IRRTB1 is cleared by writing 0 |
| 4 to 0 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                       |

### 3.2.7 Wakeup Interrupt Flag Register (IWPR)

IWPR is a status flag register for  $\overline{\text{WKP5}}$  to  $\overline{\text{WKP0}}$  interrupt requests.

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                          |
|------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7, 6 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                                                         |
| 5    | IWPF5    | 0             | R/W | WKP5 Interrupt Request Flag<br>[Setting condition]<br>When $\overline{\text{WKP5}}$ pin is designated for interrupt input and the designated signal edge is detected.<br>[Clearing condition]<br>When IWPF5 is cleared by writing 0. |
| 4    | IWPF4    | 0             | R/W | WKP4 Interrupt Request Flag<br>[Setting condition]<br>When $\overline{\text{WKP4}}$ pin is designated for interrupt input and the designated signal edge is detected.<br>[Clearing condition]<br>When IWPF4 is cleared by writing 0. |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                            |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | IWPF3    | 0             | R/W | <p>WKP3 Interrupt Request Flag</p> <p>[Setting condition]</p> <p>When <math>\overline{\text{WKP3}}</math> pin is designated for interrupt input and the designated signal edge is detected.</p> <p>[Clearing condition]</p> <p>When IWPF3 is cleared by writing 0.</p> |
| 2   | IWPF2    | 0             | R/W | <p>WKP2 Interrupt Request Flag</p> <p>[Setting condition]</p> <p>When <math>\overline{\text{WKP2}}</math> pin is designated for interrupt input and the designated signal edge is detected.</p> <p>[Clearing condition]</p> <p>When IWPF2 is cleared by writing 0.</p> |
| 1   | IWPF1    | 0             | R/W | <p>WKP1 Interrupt Request Flag</p> <p>[Setting condition]</p> <p>When <math>\overline{\text{WKP1}}</math> pin is designated for interrupt input and the designated signal edge is detected.</p> <p>[Clearing condition]</p> <p>When IWPF1 is cleared by writing 0.</p> |
| 0   | IWPF0    | 0             | R/W | <p>WKP0 Interrupt Request Flag</p> <p>[Setting condition]</p> <p>When <math>\overline{\text{WKP0}}</math> pin is designated for interrupt input and the designated signal edge is detected.</p> <p>[Clearing condition]</p> <p>When IWPF0 is cleared by writing 0.</p> |

### 3.3 Reset Exception Handling

When the  $\overline{\text{RES}}$  pin goes low, all processing halts and this LSI enters the reset. The internal state of the CPU and the registers of the on-chip peripheral modules are initialized by the reset. To ensure that this LSI is reset at power-up, hold the  $\overline{\text{RES}}$  pin low until the clock pulse generator output stabilizes. To reset the chip during operation, hold the  $\overline{\text{RES}}$  pin low for at least 10 system clock cycles. When the  $\overline{\text{RES}}$  pin goes high after being held low for the necessary time, this LSI starts reset exception handling. The reset exception handling sequence is shown in figure 3.1. However, for the reset exception handling sequence of the product with on-chip power-on reset circuit, refer to section 20, Power-On Reset and Low-Voltage Detection Circuits.

The reset exception handling sequence is as follows:

1. Set the I bit in the condition code register (CCR) to 1.
2. The CPU generates a reset exception handling vector address (from H'0000 to H'0001), the data in that address is sent to the program counter (PC) as the start address, and program execution starts from that address.

### 3.4 Interrupt Exception Handling

#### 3.4.1 External Interrupts

As the external interrupts, there are NMI, IRQ3 to IRQ0, and WKP5 to WKP0 interrupts.

##### NMI Interrupt

NMI interrupt is requested by input signal edge to pin  $\overline{\text{NMI}}$ . This interrupt is detected by either rising edge sensing or falling edge sensing, depending on the setting of bit NMIEG in IEGR1. NMI is the highest-priority interrupt, and can always be accepted without depending on the I bit value in CCR.

##### IRQ3 to IRQ0 Interrupts

IRQ3 to IRQ0 interrupts are requested by input signals to pins  $\overline{\text{IRQ3}}$  to  $\overline{\text{IRQ0}}$ . These four interrupts are given different vector addresses, and are detected individually by either rising edge sensing or falling edge sensing, depending on the settings of bits IEG3 to IEG0 in IEGR1. When pins  $\overline{\text{IRQ3}}$  to  $\overline{\text{IRQ0}}$  are designated for interrupt input in PMR1 and the designated signal edge is input, the corresponding bit in IRR1 is set to 1, requesting the CPU of an interrupt. These interrupts can be masked by setting bits IEN3 to IEN0 in IENR1.

## WKP5 to WKP0 Interrupts

WKP5 to WKP0 interrupts are requested by input signals to pins  $\overline{\text{WKP5}}$  to  $\overline{\text{WKP0}}$ . These six interrupts have the same vector addresses, and are detected individually by either rising edge sensing or falling edge sensing, depending on the settings of bits WPEG5 to WPEG0 in IEGR2.

When pins  $\overline{\text{WKP5}}$  to  $\overline{\text{WKP0}}$  are designated for interrupt input in PMR5 and the designated signal edge is input, the corresponding bit in IWPR is set to 1, requesting the CPU of an interrupt. These interrupts can be masked by setting bit IENWP in IENR1.

Figure 3.1 Reset Sequence

### 3.4.2 Internal Interrupts

Each on-chip peripheral module has a flag to show the interrupt request status and the enable bit to enable or disable the interrupt. For RTC interrupt requests and direct transfer interrupt requests generated by execution of a SLEEP instruction, this function is included in IRR1, IRR2, IENR1, and IENR2.

When an on-chip peripheral module requests an interrupt, the corresponding interrupt request status flag is set to 1, requesting the CPU of an interrupt. These interrupts can be masked by writing 0 to clear the corresponding enable bit.

### 3.4.3 Interrupt Handling Sequence

Interrupts are controlled by an interrupt controller.

Interrupt operation is described as follows.

1. If an interrupt occurs while the NMI or interrupt enable bit is set to 1, an interrupt request signal is sent to the interrupt controller.
2. When multiple interrupt requests are generated, the interrupt controller requests to the CPU for the interrupt handling with the highest priority at that time according to table 3.1. Other interrupt requests are held pending.
3. The CPU accepts the NMI and address break without depending on the I bit value. Other interrupt requests are accepted, if the I bit is cleared to 0 in CCR; if the I bit is set to 1, the interrupt request is held pending.
4. If the CPU accepts the interrupt after processing of the current instruction is completed, interrupt exception handling will begin. First, both PC and CCR are pushed onto the stack. The state of the stack at this time is shown in figure 3.2. The PC value pushed onto the stack is the address of the first instruction to be executed upon return from interrupt handling.
5. Then, the I bit of CCR is set to 1, masking further interrupts excluding the NMI and address break. Upon return from interrupt handling, the values of I bit and other bits in CCR will be restored and returned to the values prior to the start of interrupt exception handling.
6. Next, the CPU generates the vector address corresponding to the accepted interrupt, and transfers the address to PC as a start address of the interrupt handling-routine. Then a program starts executing from the address indicated in PC.

Figure 3.3 shows a typical interrupt sequence where the program area is in the on-chip ROM and the stack area is in the on-chip RAM.

**Legend:**

PCH: Upper 8 bits of program counter (PC)

PCL: Lower 8 bits of program counter (PC)

CCR: Condition code register

SP: Stack pointer

Notes: 1. PC shows the address of the first instruction to be executed upon return from the interrupt handling routine.

2. Register contents must always be saved and restored by word length, starting from an even-numbered address.

3. Ignored when returning from the interrupt handling routine.

**Figure 3.2 Stack Status after Exception Handling**

### 3.4.4 Interrupt Response Time

Table 3.2 shows the number of wait states after an interrupt request flag is set until the first instruction of the interrupt handling-routine is executed.

**Table 3.2 Interrupt Wait States**

| Item                                                  | States  | Total    |
|-------------------------------------------------------|---------|----------|
| Waiting time for completion of executing instruction* | 1 to 23 | 15 to 37 |
| Saving of PC and CCR to stack                         | 4       |          |
| Vector fetch                                          | 2       |          |
| Instruction fetch                                     | 4       |          |
| Internal processing                                   | 4       |          |

Note: \* Not including EEPMOV instruction.

Figure 3.3 Interrupt Sequence

## 3.5 Usage Notes

### 3.5.1 Interrupts after Reset

If an interrupt is accepted after a reset and before the stack pointer (SP) is initialized, the PC and CCR will not be saved correctly, leading to a program crash. To prevent this, all interrupt requests, including NMI, are disabled immediately after a reset. Since the first instruction of a program is always executed immediately after the reset state ends, make sure that this instruction initializes the stack pointer (example: MOV.W #xx: 16, SP).

### 3.5.2 Notes on Stack Area Use

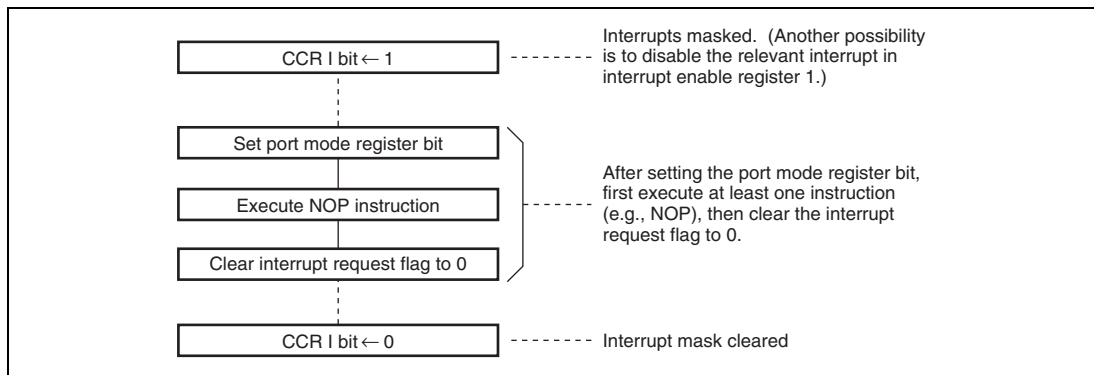

When word data is accessed, the least significant bit of the address is regarded as 0. Access to the stack always takes place in word size, so the stack pointer (SP: R7) should never indicate an odd address. Use PUSH Rn (MOV.W Rn, @-SP) or POP Rn (MOV.W @SP+, Rn) to save or restore register values.

### 3.5.3 Notes on Rewriting Port Mode Registers

When a port mode register is rewritten to switch the functions of external interrupt pins,  $\overline{\text{IRQ3}}$  to  $\overline{\text{IRQ0}}$ , and  $\overline{\text{WKP5}}$  to  $\overline{\text{WKP0}}$ , the interrupt request flag may be set to 1.

When switching a pin function, mask the interrupt before setting the bit in the port mode register. After accessing the port mode register, execute at least one instruction (e.g., NOP), then clear the interrupt request flag from 1 to 0.

Figure 3.4 shows a port mode register setting and interrupt request flag clearing procedure.

**Figure 3.4 Port Mode Register Setting and Interrupt Request Flag Clearing Procedure**

## Section 4 Address Break

The address break simplifies on-board program debugging. It requests an address break interrupt when the set break condition is satisfied. The interrupt request is not affected by the I bit of CCR. Break conditions that can be set include instruction execution at a specific address and a combination of access and data at a specific address. With the address break function, the execution start point of a program containing a bug is detected and execution is branched to the correcting program. Figure 4.1 shows a block diagram of the address break.

**Figure 4.1 Block Diagram of Address Break**

### 4.1 Register Descriptions

Address break has the following registers.

- Address break control register (ABRKCR)
- Address break status register (ABRKSR)
- Break address register (BARH, BARL)
- Break data register (BDRH, BDRL)

### 4.1.1 Address Break Control Register (ABRKCR)

ABRKCR sets address break conditions.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                         |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | RTINTE   | 1             | R/W | RTE Interrupt Enable<br><br>When this bit is 0, the interrupt immediately after executing RTE is masked and then one instruction must be executed. When this bit is 1, the interrupt is not masked.                                                                                                 |
| 6   | CSEL1    | 0             | R/W | Condition Select 1 and 0                                                                                                                                                                                                                                                                            |
| 5   | CSEL0    | 0             | R/W | These bits set address break conditions.<br>00: Instruction execution cycle<br>01: CPU data read cycle<br>10: CPU data write cycle<br>11: CPU data read/write cycle                                                                                                                                 |
| 4   | ACMP2    | 0             | R/W | Address Compare Condition Select 2 to 0                                                                                                                                                                                                                                                             |
| 3   | ACMP1    | 0             | R/W | These bits set the comparison condition between the address set in BAR and the internal address bus.                                                                                                                                                                                                |
| 2   | ACMP0    | 0             | R/W | 000: Compares 16-bit addresses<br>001: Compares upper 12-bit addresses<br>010: Compares upper 8-bit addresses<br>011: Compares upper 4-bit addresses<br>1XX: Reserved (setting prohibited)                                                                                                          |
| 1   | DCMP1    | 0             | R/W | Data Compare Condition Select 1 and 0                                                                                                                                                                                                                                                               |
| 0   | DCMP0    | 0             | R/W | These bits set the comparison condition between the data set in BDR and the internal data bus.<br>00: No data comparison<br>01: Compares lower 8-bit data between BDRL and data bus<br>10: Compares upper 8-bit data between BDRH and data bus<br>11: Compares 16-bit data between BDR and data bus |

Legend: X: Don't care.

When an address break is set in the data read cycle or data write cycle, the data bus used will depend on the combination of the byte/word access and address. Table 4.1 shows the access and data bus used. When an I/O register space with an 8-bit data bus width is accessed in word size, a byte access is generated twice. For details on data widths of each register, see section 22.1, Register Addresses (Address Order).

**Table 4.1 Access and Data Bus Used**

|                                         | Word Access  |              | Byte Access  |              |
|-----------------------------------------|--------------|--------------|--------------|--------------|
|                                         | Even Address | Odd Address  | Even Address | Odd Address  |
| ROM space                               | Upper 8 bits | Lower 8 bits | Upper 8 bits | Upper 8 bits |
| RAM space                               | Upper 8 bits | Lower 8 bits | Upper 8 bits | Upper 8 bits |
| I/O register with 8-bit data bus width  | Upper 8 bits | Upper 8 bits | Upper 8 bits | Upper 8 bits |
| I/O register with 16-bit data bus width | Upper 8 bits | Lower 8 bits | —            | —            |

#### 4.1.2 Address Break Status Register (ABRKSR)

ABRKSR consists of the address break interrupt flag and the address break interrupt enable bit.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                            |
|--------|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | ABIF     | 0             | R/W | Address Break Interrupt Flag<br>[Setting condition]<br>When the condition set in ABRKCR is satisfied<br>[Clearing condition]<br>When 0 is written after ABIF=1 is read |
| 6      | ABIE     | 0             | R/W | Address Break Interrupt Enable<br>When this bit is 1, an address break interrupt request is enabled.                                                                   |
| 5 to 0 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                           |

#### 4.1.3 Break Address Registers (BARH, BARL)

BARH and BARL are 16-bit read/write registers that set the address for generating an address break interrupt. When setting the address break condition to the instruction execution cycle, set the first byte address of the instruction. The initial value of this register is H'FFFF.

#### 4.1.4 Break Data Registers (BDRH, BDRL)

BDRH and BDRL are 16-bit read/write registers that set the data for generating an address break interrupt. BDRH is compared with the upper 8-bit data bus. BDRL is compared with the lower 8-bit data bus. When memory or registers are accessed by byte, the upper 8-bit data bus is used for even and odd addresses in the data transmission. Therefore, comparison data must be set in

BDRH for byte access. For word access, the data bus used depends on the address. See section 4.1.1, Address Break Control Register (ABRKCR), for details. The initial value of this register is undefined.

## 4.2 Operation

When the ABIF and ABIE bits in ABRKSR are set to 1, the address break function generates an interrupt request to the CPU. The ABIF bit in ABRKSR is set to 1 by the combination of the address set in BAR, the data set in BDR, and the conditions set in ABRKCR. When the interrupt request is accepted, interrupt exception handling starts after the instruction being executed ends. The address break interrupt is not masked by the I bit in CCR of the CPU.

Figures 4.2 show the operation examples of the address break interrupt setting.

**Figure 4.2 Address Break Interrupt Operation Example (1)**

When the address break is specified in the data read cycle

Register setting

- ABRKCR = H'A0
- BAR = H'025A

Program

```

0258  NOP
025A  NOP
* 025C  MOV.W @H'025A,R0
0260  NOP
0262  NOP
:      :

```

Underline indicates the address to be stacked.

**Figure 4.2 Address Break Interrupt Operation Example (2)**

## Section 5 Clock Pulse Generators

Clock oscillator circuitry (CPG: clock pulse generator) is provided on-chip, including both a system clock pulse generator and a subclock pulse generator. The system clock pulse generator consists of a system clock oscillator, a duty correction circuit, and system clock dividers. The subclock pulse generator consists of a subclock oscillator circuit and a subclock divider.

Figure 5.1 shows a block diagram of the clock pulse generators.

**Figure 5.1 Block Diagram of Clock Pulse Generators**

The basic clock signals that drive the CPU and on-chip peripheral modules are  $\phi$  and  $\phi_{SUB}$ . The system clock is divided by prescaler S to become a clock signal from  $\phi/8192$  to  $\phi/2$ , and the subclock is divided by prescaler W to become a clock signal from  $\phi_W/128$  to  $\phi_W/8$ . Both the system clock and subclock signals are provided to the on-chip peripheral modules.

## 5.1 System Clock Generator

Clock pulses can be supplied to the system clock divider either by connecting a crystal or ceramic resonator, or by providing external clock input. Figure 5.2 shows a block diagram of the system clock generator.

**Figure 5.2 Block Diagram of System Clock Generator**

### 5.1.1 Connecting Crystal Resonator

Figure 5.3 shows a typical method of connecting a crystal resonator. An AT-cut parallel-resonance crystal resonator should be used. Figure 5.4 shows the equivalent circuit of a crystal resonator. A resonator having the characteristics given in table 5.1 should be used.

**Figure 5.3 Typical Connection to Crystal Resonator**

**Figure 5.4 Equivalent Circuit of Crystal Resonator**

**Table 5.1 Crystal Resonator Parameters**

| Frequency (MHz) | 2            | 4            | 8           | 10          | 16          | 20          |
|-----------------|--------------|--------------|-------------|-------------|-------------|-------------|
| $R_s$ (max)     | 500 $\Omega$ | 120 $\Omega$ | 80 $\Omega$ | 60 $\Omega$ | 50 $\Omega$ | 40 $\Omega$ |
| $C_0$ (max)     | 7 pF         | 7 pF         | 7 pF        | 7 pF        | 7 pF        | 7 pF        |

### 5.1.2 Connecting Ceramic Resonator

Figure 5.5 shows a typical method of connecting a ceramic resonator.

**Figure 5.5 Typical Connection to Ceramic Resonator**

### 5.1.3 External Clock Input Method

Connect an external clock signal to pin OSC<sub>1</sub>, and leave pin OSC<sub>2</sub> open. Figure 5.6 shows a typical connection. The duty cycle of the external clock signal must be 45 to 55%.

**Figure 5.6 Example of External Clock Input**

## 5.2 Subclock Generator

Figure 5.7 shows a block diagram of the subclock generator.

**Figure 5.7 Block Diagram of Subclock Generator**

### 5.2.1 Connecting 32.768-kHz Crystal Resonator

Clock pulses can be supplied to the subclock divider by connecting a 32.768-kHz crystal resonator, as shown in figure 5.8. Figure 5.9 shows the equivalent circuit of the 32.768-kHz crystal resonator.

**Figure 5.8 Typical Connection to 32.768-kHz Crystal Resonator**

**Figure 5.9 Equivalent Circuit of 32.768-kHz Crystal Resonator**

### 5.2.2 Pin Connection when Not Using Subclock

When the subclock is not used, connect pin  $X_1$  to  $V_{CL}$  or  $V_{SS}$  and leave pin  $X_2$  open, as shown in figure 5.10.

Figure 5.10 Pin Connection when not Using Subclock

## 5.3 Prescalers

### 5.3.1 Prescaler S

Prescaler S is a 13-bit counter using the system clock ( $\phi$ ) as its input clock. It is incremented once per clock period. Prescaler S is initialized to H'0000 by a reset, and starts counting on exit from the reset state. In standby mode, subactive mode, and subsleep mode, the system clock pulse generator stops. Prescaler S also stops and is initialized to H'0000. The CPU cannot read or write prescaler S. The output from prescaler S is shared by the on-chip peripheral modules. The divider ratio can be set separately for each on-chip peripheral function. In active mode and sleep mode, the clock input to prescaler S is determined by the division factor designated by MA2 to MA0 in SYSCR2.

### 5.3.2 Prescaler W

Prescaler W is a 5-bit counter using a 32.768 kHz signal divided by 4 ( $\phi_w/4$ ) as its input clock. The divided output is used for clock time base operation of timer A. Prescaler W is initialized to H'00 by a reset, and starts counting on exit from the reset state. Even in standby mode, subactive mode, or subsleep mode, prescaler W continues functioning so long as clock signals are supplied to pins  $X_1$  and  $X_2$ .

## 5.4 Usage Notes

### 5.4.1 Note on Resonators

Resonator characteristics are closely related to board design and should be carefully evaluated by the user, referring to the examples shown in this section. Resonator circuit constants will differ depending on the resonator element, stray capacitance in its interconnecting circuit, and other factors. Suitable constants should be determined in consultation with the resonator element manufacturer. Design the circuit so that the resonator element never receives voltages exceeding its maximum rating.

### 5.4.2 Notes on Board Design

When using a crystal resonator (ceramic resonator), place the resonator and its load capacitors as close as possible to the  $OSC_1$  and  $OSC_2$  pins. Other signal lines should be routed away from the resonator circuit to prevent induction from interfering with correct oscillation (see figure 5.11).

**Figure 5.11 Example of Incorrect Board Design**

## Section 6 Power-Down Modes

This LSI has six modes of operation after a reset. These include a normal active mode and four power-down modes, in which power consumption is significantly reduced. Module standby mode reduces power consumption by selectively halting on-chip module functions.

- Active mode

The CPU and all on-chip peripheral modules are operable on the system clock. The system clock frequency can be selected from  $\phi_{osc}$ ,  $\phi_{osc}/8$ ,  $\phi_{osc}/16$ ,  $\phi_{osc}/32$ , and  $\phi_{osc}/64$ .

- Subactive mode

The CPU and all on-chip peripheral modules are operable on the subclock. The subclock frequency can be selected from  $\phi_w/2$ ,  $\phi_w/4$ , and  $\phi_w/8$ .

- Sleep mode

The CPU halts. On-chip peripheral modules are operable on the system clock.

- Subsleep mode

The CPU halts. On-chip peripheral modules are operable on the subclock.

- Standby mode

The CPU and all on-chip peripheral modules halt. When the clock time-base function is selected, the RTC is operable.

- Module standby mode

Independent of the above modes, power consumption can be reduced by halting on-chip peripheral modules that are not used in module units.

### 6.1 Register Descriptions

The registers related to power-down modes are listed below.

- System control register 1 (SYSCR1)
- System control register 2 (SYSCR2)
- Module standby control register 1 (MSTCR1)
- Module standby control register 2 (MSTCR2)

### 6.1.1 System Control Register 1 (SYSCR1)

SYSCR1 controls the power-down modes, as well as SYSCR2.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Legend X: Don't care.

### 6.1.3 Module Standby Control Register 1 (MSTCR1)

MSTCR1 allows the on-chip peripheral modules to enter a standby state in module units.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                             |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | 0             | —   | Reserved<br>This bit is always read as 0.                                                                                                                                                                                               |

### 6.1.4 Module Standby Control Register 2 (MSTCR2)

MSTCR2 allows the on-chip peripheral modules to enter a standby state in module units.

| Bit  | Bit Name | Initial Value | R/W | Description                                                                       |
|------|----------|---------------|-----|-----------------------------------------------------------------------------------|
| 7    | MSTS3_2  | 0             | R/W | SCI3_2 Module Standby<br>SCI3_2 enters standby mode when this bit is set to 1     |
| 6, 5 | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                      |
| 4    | MSTTB1   | 0             | R/W | Timer B1 Module Standby<br>Timer B1 enters standby mode when this bit is set to 1 |
| 3, 2 | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                      |
| 1    | MSTTZ    | 0             | R/W | Timer Z Module Standby<br>Timer Z enters standby mode when this bit is set to 1   |
| 0    | MSTPWM   | 0             | R/W | PWM Module Standby<br>PWM enters standby mode when this bit is set to 1           |

## 6.2 Mode Transitions and States of LSI

Figure 6.1 shows the possible transitions among these operating modes. A transition is made from the program execution state to the program halt state by executing a SLEEP instruction. Interrupts allow for returning from the program halt state to the program execution state. A direct transition between active mode and subactive mode, which are both program execution states, can be made without halting the program. The operating frequency can also be changed in the same modes by making a transition directly from active mode to active mode, and from subactive mode to subactive mode.  $\overline{\text{RES}}$  input enables transitions from a mode to the reset state. Table 6.2 shows the transition conditions of each mode after the SLEEP instruction is executed and a mode to return by an interrupt. Table 6.3 shows the internal states of the LSI in each mode.

- Notes: 1. To make a transition to another mode by an interrupt, make sure interrupt handling is after the interrupt is accepted.  
 2. Details on the mode transition conditions are given in table 6.2.

**Figure 6.1 Mode Transition Diagram**

**Table 6.2 Transition Mode after SLEEP Instruction Execution and Transition Mode due to Interrupt**

| DTON | SSBY | SMSEL | LSON | Transition Mode after SLEEP Instruction Execution | Transition Mode due to Interrupt |
|------|------|-------|------|---------------------------------------------------|----------------------------------|
| 0    | 0    | 0     | 0    | Sleep mode                                        | Active mode                      |
|      |      |       | 1    |                                                   | Subactive mode                   |
|      |      | 1     | 0    | Subsleep mode                                     | Active mode                      |
|      |      |       | 1    |                                                   | Subactive mode                   |
|      | 1    | X     | X    | Standby mode                                      | Active mode                      |
| 1    | X    | 0*    | 0    | Active mode (direct transition)                   | —                                |
|      | X    | X     | 1    | Subactive mode (direct transition)                | —                                |

Legend: X: Don't care.

\* When a state transition is performed while SMSEL is 1, timer V, SCI3, SCI3\_2 and the A/D converter are reset, and all registers are set to their initial values. To use these functions after entering active mode, reset the registers.

**Table 6.3 Internal State in Each Operating Mode**

| Function                |                | Active Mode | Sleep Mode  | Subactive Mode                                                                                                          | Subsleep Mode | Standby Mode                                                            |

|                         | A/D converter  | Functioning | Functioning | Reset                                                                                                                   | Reset         | Reset                                                                   |

Note: \* Registers can be read or written in subactive mode.

### 6.2.1 Sleep Mode

In sleep mode, CPU operation is halted but the on-chip peripheral modules function at the clock frequency set by the MA2, MA1, and MA0 bits in SYSCR2. CPU register contents are retained. When an interrupt is requested, sleep mode is cleared and interrupt exception handling starts. Sleep mode is not cleared if the I bit of the condition code register (CCR) is set to 1 or the requested interrupt is disabled in the interrupt enable register. After sleep mode is cleared, a transition is made to active mode when the LSON bit in SYSCR2 is 0, and a transition is made to subactive mode when the bit is 1.

When the  $\overline{\text{RES}}$  pin goes low, the CPU goes into the reset state and sleep mode is cleared.

### 6.2.2 Standby Mode

In standby mode, the clock pulse generator stops, so the CPU and on-chip peripheral modules stop functioning. However, as long as the rated voltage is supplied, the contents of CPU registers, on-chip RAM, and some on-chip peripheral module registers are retained. On-chip RAM contents will be retained as long as the voltage set by the RAM data retention voltage is provided. The I/O ports go to the high-impedance state.

Standby mode is cleared by an interrupt. When an interrupt is requested, the system clock pulse generator starts. After the time set in bits STS2 to STS0 in SYSCR1 has elapsed, and interrupt exception handling starts. Standby mode is not cleared if the I bit of CCR is set to 1 or the requested interrupt is disabled in the interrupt enable register.

When the  $\overline{\text{RES}}$  pin goes low, the system clock pulse generator starts. Since system clock signals are supplied to the entire chip as soon as the system clock pulse generator starts functioning, the  $\overline{\text{RES}}$  pin must be kept low until the pulse generator output stabilizes. After the pulse generator output has stabilized, the CPU starts reset exception handling if the RES pin is driven high.

### 6.2.3 Subsleep Mode

In subsleep mode, operation of the CPU and on-chip peripheral modules other than RTC is halted. As long as a required voltage is applied, the contents of CPU registers, the on-chip RAM, and some registers of the on-chip peripheral modules are retained. I/O ports keep the same states as before the transition.

Subsleep mode is cleared by an interrupt. When an interrupt is requested, subsleep mode is cleared and interrupt exception handling starts. Subsleep mode is not cleared if the I bit of CCR is set to 1 or the requested interrupt is disabled in the interrupt enable register. After subsleep mode is cleared, a transition is made to active mode when the LSON bit in SYSCR2 is 0, and a transition is made to subactive mode when the bit is 1. After the time set in bits STS2 to STS0 in SYSCR1 has elapsed, a transition is made to active mode.

When the  $\overline{\text{RES}}$  pin goes low, the system clock pulse generator starts. Since system clock signals are supplied to the entire chip as soon as the system clock pulse generator starts functioning, the  $\overline{\text{RES}}$  pin must be kept low until the pulse generator output stabilizes. After the pulse generator output has stabilized, the CPU starts reset exception handling if the  $\overline{\text{RES}}$  pin is driven high.

## 6.2.4 Subactive Mode

The operating frequency of subactive mode is selected from  $\phi_w/2$ ,  $\phi_w/4$ , and  $\phi_w/8$  by the SA1 and SA0 bits in SYSCR2. After the SLEEP instruction is executed, the operating frequency changes to the frequency which is set before the execution. When the SLEEP instruction is executed in subactive mode, a transition to sleep mode, subsleep mode, standby mode, active mode, or subactive mode is made, depending on the combination of SYSCR1 and SYSCR2. When the  $\overline{\text{RES}}$  pin goes low, the system clock pulse generator starts. Since system clock signals are supplied to the entire chip as soon as the system clock pulse generator starts functioning, the  $\overline{\text{RES}}$  pin must be kept low until the pulse generator output stabilizes. After the pulse generator output has stabilized, the CPU starts reset exception handling if the  $\overline{\text{RES}}$  pin is driven high.

## 6.3 Operating Frequency in Active Mode

Operation in active mode is clocked at the frequency designated by the MA2, MA1, and MA0 bits in SYSCR2. The operating frequency changes to the set frequency after SLEEP instruction execution.

## 6.4 Direct Transition

The CPU can execute programs in two modes: active and subactive modes. A direct transition is a transition between these two modes without stopping program execution. A direct transition can be made by executing a SLEEP instruction while the DTON bit in SYSCR2 is set to 1. The direct transition also enables operating frequency modification in active or subactive mode. After the mode transition, direct transition interrupt exception handling starts.

If the direct transition interrupt is disabled in interrupt enable register 1, a transition is made instead to sleep or subsleep mode. Note that if a direct transition is attempted while the I bit in CCR is set to 1, sleep or subsleep mode will be entered, and the resulting mode cannot be cleared by means of an interrupt.

### 6.4.1 Direct Transition from Active Mode to Subactive Mode

The time from the start of SLEEP instruction execution to the end of interrupt exception handling (the direct transition time) is calculated by equation (1).

Direct transition time = {(number of SLEEP instruction execution states) + (number of internal processing states)}  $\times$  (tcyc before transition) + (number of interrupt exception handling states)  $\times$  (tsubcyc after transition) (1)

#### Example

Direct transition time =  $(2 + 1) \times \text{tosc} + 14 \times 8\text{tw} = 3\text{tosc} + 112\text{tw}$   
(when the CPU operating clock of  $\phi_{\text{osc}} \rightarrow \phi_w/8$  is selected)

**Legend**

tosc: OSC clock cycle time

tw: Watch clock cycle time

tcyc: System clock ( $\phi$ ) cycle timetsubcyc: Subclock ( $\phi_{\text{SUB}}$ ) cycle time**6.4.2 Direct Transition from Subactive Mode to Active Mode**

The time from the start of SLEEP instruction execution to the end of interrupt exception handling (the direct transition time) is calculated by equation (2).

Direct transition time = {(number of SLEEP instruction execution states) + (number of internal processing states)}  $\times$  (tsubcyc before transition) + {(waiting time set in bits STS2 to STS0) + (number of interrupt exception handling states)}  $\times$  (tcyc after transition) (2)

**Example**

Direct transition time =  $(2 + 1) \times 8tw + (8192 + 14) \times tosc = 24tw + 8206tosc$

(when the CPU operating clock of  $\phi_w/8 \rightarrow \phi_{osc}$  and a waiting time of 8192 states are selected)

**Legend**

tosc: OSC clock cycle time

tw: Watch clock cycle time

tcyc: System clock ( $\phi$ ) cycle timetsubcyc: Subclock ( $\phi_{\text{SUB}}$ ) cycle time**6.5 Module Standby Function**

The module-standby function can be set to any peripheral module. In module standby mode, the clock supply to modules stops to enter the power-down mode. Module standby mode enables each on-chip peripheral module to enter the standby state by setting a bit that corresponds to each module to 1 and cancels the mode by clearing the bit to 0.

# Section 7 ROM

The features of the 56-kbyte or 32-kbyte flash memories built into the flash memory (F-ZTAT) version are summarized below.

- Programming/erase methods
  - The flash memory is programmed 128 bytes at a time. Erase is performed in single-block units. The flash memory is configured as follows: 1 kbyte  $\times$  4 blocks, 28 kbytes  $\times$  1 block, 16 kbytes  $\times$  1 block, and 8 kbytes  $\times$  1 block for H8/3687F and 1 kbyte  $\times$  4 blocks and 28 kbytes  $\times$  1 block for H8/3684F. To erase the entire flash memory, each block must be erased in turn.
- Reprogramming capability
  - The flash memory can be reprogrammed up to 1,000 times.
- On-board programming
  - On-board programming/erasing can be done in boot mode, in which the boot program built into the chip is started to erase or program of the entire flash memory. In normal user program mode, individual blocks can be erased or programmed.
- Programmer mode
  - Flash memory can be programmed/erased in programmer mode using a PROM programmer, as well as in on-board programming mode.
- Automatic bit rate adjustment
  - For data transfer in boot mode, this LSI's bit rate can be automatically adjusted to match the transfer bit rate of the host.
- Programming/erasing protection
  - Sets software protection against flash memory programming/erasing.
- Power-down mode
  - Operation of the power supply circuit can be partly halted in subactive mode. As a result, flash memory can be read with low power consumption.

## 7.1 Block Configuration

Figure 7.1 shows the block configuration of flash memory. The thick lines indicate erasing units, the narrow lines indicate programming units, and the values are addresses. The 56-kbyte flash memory is divided into 1 kbyte  $\times$  4 blocks, 28 kbytes  $\times$  1 block, 16 kbytes  $\times$  1 block, and 8 kbytes  $\times$  1 block. The 32-kbyte flash memory is divided into 1 kbyte  $\times$  4 blocks and 28 kbytes  $\times$  1 blocks. Erasing is performed in these units. Programming is performed in 128-byte units starting from an address with lower eight bits H'00 or H'80.

**Figure 7.1 Flash Memory Block Configuration**

## 7.2 Register Descriptions

The flash memory has the following registers.

- Flash memory control register 1 (FLMCR1)
- Flash memory control register 2 (FLMCR2)
- Erase block register 1 (EBR1)
- Flash memory power control register (FLPWCR)
- Flash memory enable register (FENR)

### 7.2.1 Flash Memory Control Register 1 (FLMCR1)

FLMCR1 is a register that makes the flash memory change to program mode, program-verify mode, erase mode, or erase-verify mode. For details on register setting, refer to section 7.4, Flash Memory Programming/Erasing.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                           |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | 0             | —   | Reserved<br>This bit is always read as 0.                                                                                                                                                                             |
| 6   | SWE      | 0             | R/W | Software Write Enable<br>When this bit is set to 1, flash memory programming/erasing is enabled. When this bit is cleared to 0, other FLMCR1 register bits and all EBR1 bits cannot be set.                           |
| 5   | ESU      | 0             | R/W | Erase Setup<br>When this bit is set to 1, the flash memory changes to the erase setup state. When it is cleared to 0, the erase setup state is cancelled. Set this bit to 1 before setting the E bit to 1 in FLMCR1.  |
| 4   | PSU      | 0             | R/W | Program Setup<br>When this bit is set to 1, the flash memory changes to the program setup state. When it is cleared to 0, the program setup state is cancelled. Set this bit to 1 before setting the P bit in FLMCR1. |
| 3   | EV       | 0             | R/W | Erase-Verify<br>When this bit is set to 1, the flash memory changes to erase-verify mode. When it is cleared to 0, erase-verify mode is cancelled.                                                                    |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                      |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | PV       | 0             | R/W | <b>Program-Verify</b><br>When this bit is set to 1, the flash memory changes to program-verify mode. When it is cleared to 0, program-verify mode is cancelled.  |
| 1   | E        | 0             | R/W | <b>Erase</b><br>When this bit is set to 1 while SWE=1 and ESU=1, the flash memory changes to erase mode. When it is cleared to 0, erase mode is cancelled.       |
| 0   | P        | 0             | R/W | <b>Program</b><br>When this bit is set to 1 while SWE=1 and PSU=1, the flash memory changes to program mode. When it is cleared to 0, program mode is cancelled. |

### 7.2.2 Flash Memory Control Register 2 (FLMCR2)

FLMCR2 is a register that displays the state of flash memory programming/erasing. FLMCR2 is a read-only register, and should not be written to.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                  |
|--------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | FLER     | 0             | R   | <b>Flash Memory Error</b><br>Indicates that an error has occurred during an operation on flash memory (programming or erasing). When FLER is set to 1, flash memory goes to the error-protection state.<br>See section 7.5.3, Error Protection, for details. |
| 6 to 0 | —        | All 0         | —   | <b>Reserved</b><br>These bits are always read as 0.                                                                                                                                                                                                          |

### 7.2.3 Erase Block Register 1 (EBR1)

EBR1 specifies the flash memory erase area block. EBR1 is initialized to H'00 when the SWE bit in FLMCR1 is 0. Do not set more than one bit at a time, as this will cause all the bits in EBR1 to be automatically cleared to 0.

| Bit | Bit Name | Initial Value | R/W | Description                                                              |
|-----|----------|---------------|-----|--------------------------------------------------------------------------|
| 7   | —        | 0             | —   | Reserved<br>This bit is always read as 0.                                |
| 6   | EB6      | 0             | R/W | When this bit is set to 1, 8 bytes of H'C000 to H'DFFF will be erased.   |
| 5   | EB5      | 0             | R/W | When this bit is set to 1, 16 bytes of H'8000 to H'BFFF will be erased.  |
| 4   | EB4      | 0             | R/W | When this bit is set to 1, 28 kbytes of H'1000 to H'7FFF will be erased. |
| 3   | EB3      | 0             | R/W | When this bit is set to 1, 1 kbyte of H'0C00 to H'0FFF will be erased.   |
| 2   | EB2      | 0             | R/W | When this bit is set to 1, 1 kbyte of H'0800 to H'0BFF will be erased.   |
| 1   | EB1      | 0             | R/W | When this bit is set to 1, 1 kbyte of H'0400 to H'07FF will be erased.   |
| 0   | EB0      | 0             | R/W | When this bit is set to 1, 1 kbyte of H'0000 to H'03FF will be erased.   |

## 7.2.4 Flash Memory Power Control Register (FLPWCR)

FLPWCR enables or disables a transition to the flash memory power-down mode when the LSI switches to subactive mode. There are two modes: mode in which operation of the power supply circuit of flash memory is partly halted in power-down mode and flash memory can be read, and mode in which even if a transition is made to subactive mode, operation of the power supply circuit of flash memory is retained and flash memory can be read.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                              |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | PDWND    | 0             | R/W | Power-Down Disable<br><br>When this bit is 0 and a transition is made to subactive mode, the flash memory enters the power-down mode. When this bit is 1, the flash memory remains in the normal mode even after a transition is made to subactive mode. |
| 6 to 0 | —        | All 0         | —   | Reserved<br><br>These bits are always read as 0.                                                                                                                                                                                                         |

## 7.2.5 Flash Memory Enable Register (FENR)

Bit 7 (FLSHE) in FENR enables or disables the CPU access to the flash memory control registers, FLMCR1, FLMCR2, EBR1, and FLPWCR.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                        |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | FLSHE    | 0             | R/W | Flash Memory Control Register Enable<br><br>Flash memory control registers can be accessed when this bit is set to 1. Flash memory control registers cannot be accessed when this bit is set to 0. |
| 6 to 0 | —        | All 0         | —   | Reserved<br><br>These bits are always read as 0.                                                                                                                                                   |

## 7.3 On-Board Programming Modes

There are two modes for programming/erasing of the flash memory; boot mode, which enables on-board programming/erasing, and programmer mode, in which programming/erasing is performed with a PROM programmer. On-board programming/erasing can also be performed in user program mode. At reset-start in reset mode, this LSI changes to a mode depending on the TEST pin settings,  $\overline{\text{NMI}}$  pin settings, and input level of each port, as shown in table 7.1. The input level of each pin must be defined four states before the reset ends.

When changing to boot mode, the boot program built into this LSI is initiated. The boot program transfers the programming control program from the externally-connected host to on-chip RAM via SCI3. After erasing the entire flash memory, the programming control program is executed. This can be used for programming initial values in the on-board state or for a forcible return when programming/erasing can no longer be done in user program mode. In user program mode, individual blocks can be erased and programmed by branching to the user program/erase control program prepared by the user.

**Table 7.1 Setting Programming Modes**

| TEST | $\overline{\text{NMI}}$ | P85 | PB0 | PB1 | PB2 | LSI State after Reset End |
|------|-------------------------|-----|-----|-----|-----|---------------------------|
| 0    | 1                       | X   | X   | X   | X   | User Mode                 |
| 0    | 0                       | 1   | X   | X   | X   | Boot Mode                 |
| 1    | X                       | X   | 0   | 0   | 0   | Programmer Mode           |

Legend: X : Don't care.

### 7.3.1 Boot Mode

Table 7.2 shows the boot mode operations between reset end and branching to the programming control program.

1. When boot mode is used, the flash memory programming control program must be prepared in the host beforehand. Prepare a programming control program in accordance with the description in section 7.4, Flash Memory Programming/Erasing.
2. SCI3 should be set to asynchronous mode, and the transfer format as follows: 8-bit data, 1 stop bit, and no parity.
3. When the boot program is initiated, the chip measures the low-level period of asynchronous SCI communication data (H'00) transmitted continuously from the host. The chip then calculates the bit rate of transmission from the host, and adjusts the SCI3 bit rate to match that of the host. The reset should end with the RxD pin high. The RxD and TxD pins should be pulled up on the board if necessary. After the reset is complete, it takes approximately 100 states before the chip is ready to measure the low-level period.

4. After matching the bit rates, the chip transmits one H'00 byte to the host to indicate the completion of bit rate adjustment. The host should confirm that this adjustment end indication (H'00) has been received normally, and transmit one H'55 byte to the chip. If reception could not be performed normally, initiate boot mode again by a reset. Depending on the host's transfer bit rate and system clock frequency of this LSI, there will be a discrepancy between the bit rates of the host and the chip. To operate the SCI properly, set the host's transfer bit rate and system clock frequency of this LSI within the ranges listed in table 7.3.
5. In boot mode, a part of the on-chip RAM area is used by the boot program. The area H'F780 to H'FEFF is the area to which the programming control program is transferred from the host. The boot program area cannot be used until the execution state in boot mode switches to the programming control program.
6. Before branching to the programming control program, the chip terminates transfer operations by SCI3 (by clearing the RE and TE bits in SCR to 0), however the adjusted bit rate value remains set in BRR. Therefore, the programming control program can still use it for transfer of program data or verify data with the host. The TxD pin is high (PCR22 = 1, P22 = 1). The contents of the CPU general registers are undefined immediately after branching to the programming control program. These registers must be initialized at the beginning of the programming control program, as the stack pointer (SP), in particular, is used implicitly in subroutine calls, etc.
7. Boot mode can be cleared by a reset. End the reset after driving the reset pin low, waiting at least 20 states, and then setting the  $\overline{\text{NMI}}$  pin. Boot mode is also cleared when a WDT overflow occurs.
8. Do not change the TEST pin and  $\overline{\text{NMI}}$  pin input levels in boot mode.

**Table 7.2 Boot Mode Operation**

| Item                                                       | Host Operation                                                                                                                                                                                                                                      | Communication Contents                                                                  | LSI Operation                                                                                                                                                                                                                                  |
|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                            | Processing Contents                                                                                                                                                                                                                                 |                                                                                         | Processing Contents                                                                                                                                                                                                                            |
| Boot mode initiation                                       |                                                                                                                                                                                                                                                     |                                                                                         | <p>Branches to boot program at reset-start.</p> <p>Boot program initiation</p>                                                                                                                                                                 |
| Bit rate adjustment                                        | <p>Continuously transmits data H'00 at specified bit rate.</p> <p>Transmits data H'55 when data H'00 is received error-free.</p>                                                                                                                    | <p>H'00, H'00 . . . H'00</p> <p>H'00</p> <p>H'55</p>                                    | <ul style="list-style-type: none"> <li>Measures low-level period of receive data H'00.</li> <li>Calculates bit rate and sets BRR in SCI3.</li> <li>Transmits data H'00 to host as adjustment end indication.</li> </ul> <p>H'55 reception.</p> |

|                                                            |                                                                                                                                                                                                                                                     |                                                                                         | <p>Branches to programming control program transferred to on-chip RAM and starts execution.</p>                                                                                                                                                |

**Table 7.3 System Clock Frequencies for which Automatic Adjustment of LSI Bit Rate is Possible**

| Host Bit Rate | System Clock Frequency Range of LSI |
|---------------|-------------------------------------|
| 19,200 bps    | 16 to 20 MHz                        |
| 9,600 bps     | 8 to 16 MHz                         |
| 4,800 bps     | 4 to 16 MHz                         |
| 2,400 bps     | 2 to 16 MHz                         |

### 7.3.2 Programming/Erasing in User Program Mode

On-board programming/erasing of an individual flash memory block can also be performed in user program mode by branching to a user program/erase control program. The user must set branching conditions and provide on-board means of supplying programming data. The flash memory must contain the user program/erase control program or a program that provides the user program/erase control program from external memory. As the flash memory itself cannot be read during programming/erasing, transfer the user program/erase control program to on-chip RAM, as in boot mode. Figure 7.2 shows a sample procedure for programming/erasing in user program mode. Prepare a user program/erase control program in accordance with the description in section 7.4, Flash Memory Programming/Erasing.

**Figure 7.2 Programming/Erasing Flowchart Example in User Program Mode**

## 7.4 Flash Memory Programming/Erasing

A software method using the CPU is employed to program and erase flash memory in the on-board programming modes. Depending on the FLMCR1 setting, the flash memory operates in one of the following four modes: Program mode, program-verify mode, erase mode, and erase-verify mode. The programming control program in boot mode and the user program/erase control program in user program mode use these operating modes in combination to perform programming/erasing. Flash memory programming and erasing should be performed in accordance with the descriptions in section 7.4.1, Program/Program-Verify and section 7.4.2, Erase/Erase-Verify, respectively.

### 7.4.1 Program/Program-Verify

When writing data or programs to the flash memory, the program/program-verify flowchart shown in figure 7.3 should be followed. Performing programming operations according to this flowchart will enable data or programs to be written to the flash memory without subjecting the chip to voltage stress or sacrificing program data reliability.

1. Programming must be done to an empty address. Do not reprogram an address to which programming has already been performed.
2. Programming should be carried out 128 bytes at a time. A 128-byte data transfer must be performed even if writing fewer than 128 bytes. In this case, H'FF data must be written to the extra addresses.
3. Prepare the following data storage areas in RAM: A 128-byte programming data area, a 128-byte reprogramming data area, and a 128-byte additional-programming data area. Perform reprogramming data computation according to table 7.4, and additional programming data computation according to table 7.5.
4. Consecutively transfer 128 bytes of data in byte units from the reprogramming data area or additional-programming data area to the flash memory. The program address and 128-byte data are latched in the flash memory. The lower 8 bits of the start address in the flash memory destination area must be H'00 or H'80.
5. The time during which the P bit is set to 1 is the programming time. Table 7.6 shows the allowable programming times.
6. The watchdog timer (WDT) is set to prevent overprogramming due to program runaway, etc. An overflow cycle of approximately 6.6 ms is allowed.
7. For a dummy write to a verify address, write 1-byte data H'FF to an address whose lower 2 bits are B'00. Verify data can be read in words or in longwords from the address to which a dummy write was performed.
8. The maximum number of repetitions of the program/program-verify sequence of the same bit is 1,000.

**Figure 7.3 Program/Program-Verify Flowchart**

**Table 7.4 Reprogram Data Computation Table**

| Program Data | Verify Data | Reprogram Data | Comments                |
|--------------|-------------|----------------|-------------------------|
| 0            | 0           | 1              | Programming completed   |
| 0            | 1           | 0              | Reprogram bit           |
| 1            | 0           | 1              | —                       |
| 1            | 1           | 1              | Remains in erased state |

**Table 7.5 Additional-Program Data Computation Table**

| Reprogram Data | Verify Data | Additional-Program Data | Comments                  |
|----------------|-------------|-------------------------|---------------------------|
| 0              | 0           | 0                       | Additional-program bit    |
| 0              | 1           | 1                       | No additional programming |
| 1              | 0           | 1                       | No additional programming |
| 1              | 1           | 1                       | No additional programming |

**Table 7.6 Programming Time**

| n<br>(Number of Writes) | Programming Time | In Additional Programming | Comments |
|-------------------------|------------------|---------------------------|----------|
| 1 to 6                  | 30               | 10                        |          |
| 7 to 1,000              | 200              | —                         |          |

Note: Time shown in  $\mu$ s.

### 7.4.2 Erase/Erase-Verify

When erasing flash memory, the erase/erase-verify flowchart shown in figure 7.4 should be followed.

1. Prewriting (setting erase block data to all 0s) is not necessary.
2. Erasing is performed in block units. Make only a single-bit specification in the erase block register (EBR1). To erase multiple blocks, each block must be erased in turn.
3. The time during which the E bit is set to 1 is the flash memory erase time.
4. The watchdog timer (WDT) is set to prevent overerasing due to program runaway, etc. An overflow cycle of approximately 19.8 ms is allowed.
5. For a dummy write to a verify address, write 1-byte data H'FF to an address whose lower two bits are B'00. Verify data can be read in longwords from the address to which a dummy write was performed.

6. If the read data is not erased successfully, set erase mode again, and repeat the erase/erase-verify sequence as before. The maximum number of repetitions of the erase/erase-verify sequence is 100.

### **7.4.3 Interrupt Handling when Programming/Erasing Flash Memory**

All interrupts, including the NMI interrupt, are disabled while flash memory is being programmed or erased, or while the boot program is executing, for the following three reasons:

1. Interrupt during programming/erasing may cause a violation of the programming or erasing algorithm, with the result that normal operation cannot be assured.
2. If interrupt exception handling starts before the vector address is written or during programming/erasing, a correct vector cannot be fetched and the CPU malfunctions.
3. If an interrupt occurs during boot program execution, normal boot mode sequence cannot be carried out.

Note: \*The RTS instruction must not be used during a period between dummy writing of H'FF to a verify address and verify data reading.

**Figure 7.4 Erase/Eraser-Verify Flowchart**

## 7.5 Program/Erase Protection

There are three kinds of flash memory program/erase protection; hardware protection, software protection, and error protection.

### 7.5.1 Hardware Protection

Hardware protection refers to a state in which programming/erasing of flash memory is forcibly disabled or aborted because of a transition to reset, subactive mode, subsleep mode, or standby mode. Flash memory control register 1 (FLMCR1), flash memory control register 2 (FLMCR2), and erase block register 1 (EBR1) are initialized. In a reset via the  $\overline{\text{RES}}$  pin, the reset state is not entered unless the  $\overline{\text{RES}}$  pin is held low until oscillation stabilizes after powering on. In the case of a reset during operation, hold the  $\overline{\text{RES}}$  pin low for the  $\overline{\text{RES}}$  pulse width specified in the AC Characteristics section.

### 7.5.2 Software Protection

Software protection can be implemented against programming/erasing of all flash memory blocks by clearing the SWE bit in FLMCR1. When software protection is in effect, setting the P or E bit in FLMCR1 does not cause a transition to program mode or erase mode. By setting the erase block register 1 (EBR1), erase protection can be set for individual blocks. When EBR1 is set to H'00, erase protection is set for all blocks.

### 7.5.3 Error Protection

In error protection, an error is detected when CPU runaway occurs during flash memory programming/erasing, or operation is not performed in accordance with the program/erase algorithm, and the program/erase operation is forcibly aborted. Aborting the program/erase operation prevents damage to the flash memory due to overprogramming or overerasing.

When the following errors are detected during programming/erasing of flash memory, the FLER bit in FLMCR2 is set to 1, and the error protection state is entered.

- When the flash memory of the relevant address area is read during programming/erasing (including vector read and instruction fetch)
- Immediately after exception handling excluding a reset during programming/erasing
- When a SLEEP instruction is executed during programming/erasing

The FLMCR1, FLMCR2, and EBR1 settings are retained, however program mode or erase mode is aborted at the point at which the error occurred. Program mode or erase mode cannot be re-entered by re-setting the P or E bit. However, PV and EV bit settings are retained, and a transition can be made to verify mode. Error protection can be cleared only by a reset.

## 7.6 Programmer Mode

In programmer mode, a PROM programmer can be used to perform programming/erasing via a socket adapter, just as a discrete flash memory. Use a PROM programmer that supports the MCU device type with the on-chip 64-kbyte flash memory (FZTAT64V5).

## 7.7 Power-Down States for Flash Memory

In user mode, the flash memory will operate in either of the following states:

- Normal operating mode  
The flash memory can be read and written to at high speed.
- Power-down operating mode  
The power supply circuit of flash memory can be partly halted. As a result, flash memory can be read with low power consumption.
- Standby mode  
All flash memory circuits are halted.

Table 7.7 shows the correspondence between the operating modes of this LSI and the flash memory. In subactive mode, the flash memory can be set to operate in power-down mode with the PDWND bit in FLPWCR. When the flash memory returns to its normal operating state from power-down mode or standby mode, a period to stabilize operation of the power supply circuits that were stopped is needed. When the flash memory returns to its normal operating state, bits STS2 to STS0 in SYSCR1 must be set to provide a wait time of at least 20  $\mu$ s, even when the external clock is being used.

**Table 7.7 Flash Memory Operating States**

| LSI Operating State | Flash Memory Operating State |                       |
|---------------------|------------------------------|-----------------------|
|                     | PDWND = 0 (Initial Value)    | PDWND = 1             |
| Active mode         | Normal operating mode        | Normal operating mode |
| Subactive mode      | Power-down mode              | Normal operating mode |

## Section 8 RAM

This LSI has an on-chip high-speed static RAM. The RAM is connected to the CPU by a 16-bit data bus, enabling two-state access by the CPU to both byte data and word data.

| Product Classification                    |                      |          | RAM Size | RAM Address                         |
|-------------------------------------------|----------------------|----------|----------|-------------------------------------|
| Flash memory version<br>(F-ZTAT™ version) |                      | H8/3687F | 4 kbytes | H'E800 to H'FFFF, H'F780 to H'FF7F* |
|                                           |                      | H8/3684F | 4 kbytes | H'E800 to H'FFFF, H'F780 to H'FF7F* |
| Mask-ROM version                          |                      | H8/3687  | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |
|                                           |                      | H8/3686  | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |
|                                           |                      | H8/3685  | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |
|                                           |                      | H8/3684  | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |
|                                           |                      | H8/3683  | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |
|                                           |                      | H8/3682  | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |
| EEPROM stacked version                    | Flash memory version | H8/3687N | 4 kbytes | H'E800 to H'FFFF, H'F780 to H'FF7F* |
|                                           | Mask-ROM version     |          | 3 kbytes | H'E800 to H'FFFF, H'FB80 to H'FF7F  |

Note: \* When the E10T or the E7 is used, area H'F780 to H'FB7F must not be accessed.

## Section 9 I/O Ports

The group of this LSI has forty-five general I/O ports (forty-three general I/O ports in the H8/3687N) and eight general input-only ports. Port 6 is a large current port, which can drive 20 mA (@  $V_{OL} = 1.5\text{ V}$ ) when a low level signal is output. Any of these ports can become an input port immediately after a reset. They can also be used as I/O pins of the on-chip peripheral modules or external interrupt input pins, and these functions can be switched depending on the register settings. The registers for selecting these functions can be divided into two types: those included in I/O ports and those included in each on-chip peripheral module. General I/O ports are comprised of the port control register for controlling inputs/outputs and the port data register for storing output data and can select inputs/outputs in bit units.

For functions in each port, see appendix B.1, I/O Port Block Diagrams. For the execution of bit-manipulation instructions to the port control register and port data register, see section 2.8.3, Bit Manipulation Instruction.

### 9.1 Port 1

Port 1 is a general I/O port also functioning as IRQ interrupt input pins, an RTC output pin, a 14-bit PWM output pin, a timer B1 input pin, and a timer V input pin. Figure 9.1 shows its pin configuration.

**Figure 9.1 Port 1 Pin Configuration**

Port 1 has the following registers.

- Port mode register 1 (PMR1)
- Port control register 1 (PCR1)
- Port data register 1 (PDR1)
- Port pull-up control register 1 (PUCR1)

### 9.1.1 Port Mode Register 1 (PMR1)

PMR1 switches the functions of pins in port 1 and port 2.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                       |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | IRQ3     | 0             | R/W | This bit selects the function of pin P17/ $\overline{\text{IRQ3}}$ /TRGV.<br>0: General I/O port<br>1: $\overline{\text{IRQ3}}$ /TRGV input pin   |
| 6   | IRQ2     | 0             | R/W | This bit selects the function of pin P16/ $\overline{\text{IRQ2}}$ .<br>0: General I/O port<br>1: $\overline{\text{IRQ2}}$ input pin              |
| 5   | IRQ1     | 0             | R/W | This bit selects the function of pin P15/ $\overline{\text{IRQ1}}$ /TMIB1.<br>0: General I/O port<br>1: $\overline{\text{IRQ1}}$ /TMIB1 input pin |
| 4   | IRQ0     | 0             | R/W | This bit selects the function of pin P14/ $\overline{\text{IRQ0}}$ .<br>0: General I/O port<br>1: $\overline{\text{IRQ0}}$ input pin              |
| 3   | TXD2     | 0             | R/W | This bit selects the function of pin P72/TXD_2.<br>0: General I/O port<br>1: TXD_2 output pin                                                     |
| 2   | PWM      | 0             | R/W | This bit selects the function of pin P11/PWM.<br>0: General I/O port<br>1: PWM output pin                                                         |
| 1   | TXD      | 0             | R/W | This bit selects the function of pin P22/TXD.<br>0: General I/O port<br>1: TXD output pin                                                         |
| 0   | TMOW     | 0             | R/W | This bit selects the function of pin P10/TMOW.<br>0: General I/O port<br>1: TMOW output pin                                                       |

### 9.1.2 Port Control Register 1 (PCR1)

PCR1 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 1.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                     |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | PCR17    | 0             | W   | When the corresponding pin is designated in PMR1 as a general I/O pin, setting a PCR1 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port.<br>Bit 3 is a reserved bit. |
| 6   | PCR16    | 0             | W   |                                                                                                                                                                                                                                 |
| 5   | PCR15    | 0             | W   |                                                                                                                                                                                                                                 |
| 4   | PCR14    | 0             | W   |                                                                                                                                                                                                                                 |
| 3   | —        | —             | —   |                                                                                                                                                                                                                                 |
| 2   | PCR12    | 0             | W   |                                                                                                                                                                                                                                 |
| 1   | PCR11    | 0             | W   |                                                                                                                                                                                                                                 |
| 0   | PCR10    | 0             | W   |                                                                                                                                                                                                                                 |

### 9.1.3 Port Data Register 1 (PDR1)

PDR1 is a general I/O port data register of port 1.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                    |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | P17      | 0             | R/W | PDR1 stores output data for port 1 pins.<br>If PDR1 is read while PCR1 bits are set to 1, the value stored in PDR1 are read. If PDR1 is read while PCR1 bits are cleared to 0, the pin states are read regardless of the value stored in PDR1. |
| 6   | P16      | 0             | R/W |                                                                                                                                                                                                                                                |
| 5   | P15      | 0             | R/W |                                                                                                                                                                                                                                                |
| 4   | P14      | 0             | R/W |                                                                                                                                                                                                                                                |
| 3   | —        | 1             | —   | Bit 3 is a reserved bit. This bit is always read as 1.                                                                                                                                                                                         |
| 2   | P12      | 0             | R/W |                                                                                                                                                                                                                                                |
| 1   | P11      | 0             | R/W |                                                                                                                                                                                                                                                |
| 0   | P10      | 0             | R/W |                                                                                                                                                                                                                                                |

### 9.1.4 Port Pull-Up Control Register 1 (PUCR1)

PUCR1 controls the pull-up MOS in bit units of the pins set as the input ports.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                        |
|-----|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | PUCR17   | 0             | R/W | Only bits for which PCR1 is cleared are valid. The pull-up MOS of P17 to P14 and P12 to P10 pins enter the on-state when these bits are set to 1, while they enter the off-state when these bits are cleared to 0. |
| 6   | PUCR16   | 0             | R/W |                                                                                                                                                                                                                    |
| 5   | PUCR15   | 0             | R/W |                                                                                                                                                                                                                    |
| 4   | PUCR14   | 0             | R/W |                                                                                                                                                                                                                    |
| 3   | —        | 1             | —   | Bit 3 is a reserved bit. This bit is always read as 1.                                                                                                                                                             |
| 2   | PUCR12   | 0             | R/W |                                                                                                                                                                                                                    |
| 1   | PUCR11   | 0             | R/W |                                                                                                                                                                                                                    |
| 0   | PUCR10   | 0             | R/W |                                                                                                                                                                                                                    |

### 9.1.5 Pin Functions

The correspondence between the register specification and the port functions is shown below.

#### P17/ $\overline{\text{IRQ3}}$ /TRGV pin

| Register      | PMR1 | PCR1  |                                               |
|---------------|------|-------|-----------------------------------------------|
| Bit Name      | IRQ3 | PCR17 | Pin Function                                  |
| Setting value | 0    | 0     | P17 input pin                                 |
|               |      | 1     | P17 output pin                                |
|               | 1    | X     | $\overline{\text{IRQ3}}$ input/TRGV input pin |

Legend X: Don't care.

#### P16/ $\overline{\text{IRQ2}}$ pin

| Register      | PMR1 | PCR1  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | IRQ2 | PCR16 | Pin Function                       |
| Setting value | 0    | 0     | P16 input pin                      |
|               |      | 1     | P16 output pin                     |
|               | 1    | X     | $\overline{\text{IRQ2}}$ input pin |

Legend X: Don't care.

### P15/ $\overline{\text{IRQ1}}$ /TMIB1 pin

| Register      | PMR1 | PCR1  |                                                |
|---------------|------|-------|------------------------------------------------|
| Bit Name      | IRQ1 | PCR15 | Pin Function                                   |
| Setting value | 0    | 0     | P15 input pin                                  |
|               |      | 1     | P15 output pin                                 |
|               | 1    | X     | $\overline{\text{IRQ1}}$ input/TMIB1 input pin |

Legend X: Don't care.

### P14/ $\overline{\text{IRQ0}}$ pin

| Register      | PMR1 | PCR1  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | IRQ0 | PCR14 | Pin Function                       |
| Setting value | 0    | 0     | P14 input pin                      |
|               |      | 1     | P14 output pin                     |
|               | 1    | X     | $\overline{\text{IRQ0}}$ input pin |

Legend X: Don't care.

### P12 pin

| Register      | PCR1  |                |
|---------------|-------|----------------|
| Bit Name      | PCR12 | Pin Function   |
| Setting value | 0     | P12 input pin  |
|               | 1     | P12 output pin |

### P11/PWM pin

| Register      | PMR1 | PCR1  |                |
|---------------|------|-------|----------------|
| Bit Name      | PWM  | PCR11 | Pin Function   |
| Setting value | 0    | 0     | P11 input pin  |
|               |      | 1     | P11 output pin |
|               | 1    | X     | PWM output pin |

Legend X: Don't care.

### P10/TMOW pin

| Register      | PMR1 | PCR1  |                 |
|---------------|------|-------|-----------------|
| Bit Name      | TMOW | PCR10 | Pin Function    |
| Setting value | 0    | 0     | P10 input pin   |
|               |      | 1     | P10 output pin  |
|               | 1    | X     | TMOW output pin |

Legend X: Don't care.

## 9.2 Port 2

Port 2 is a general I/O port also functioning as SCI3 I/O pins. Each pin of the port 2 is shown in figure 9.2. The register settings of PMR1 and SCI3 have priority for functions of the pins for both uses.

**Figure 9.2 Port 2 Pin Configuration**

Port 2 has the following registers.

- Port control register 2 (PCR2)
- Port data register 2 (PDR2)
- Port mode register 3 (PMR3)

### 9.2.1 Port Control Register 2 (PCR2)

PCR2 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 2.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                           |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 5 | —        | —             | —   | Reserved                                                                                                                                                                                              |
| 4      | PCR24    | 0             | W   | When each of the port 2 pins P24 to P20 functions as a general I/O port, setting a PCR2 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port. |
| 3      | PCR23    | 0             | W   |                                                                                                                                                                                                       |
| 2      | PCR22    | 0             | W   |                                                                                                                                                                                                       |
| 1      | PCR21    | 0             | W   |                                                                                                                                                                                                       |
| 0      | PCR20    | 0             | W   |                                                                                                                                                                                                       |

### 9.2.2 Port Data Register 2 (PDR2)

PDR2 is a general I/O port data register of port 2.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                       |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 5 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                      |
| 4      | P24      | 0             | R/W | PDR2 stores output data for port 2 pins.                                                                                                                                                          |
| 3      | P23      | 0             | R/W | If PDR2 is read while PCR2 bits are set to 1, the value stored in PDR2 is read. If PDR2 is read while PCR2 bits are cleared to 0, the pin states are read regardless of the value stored in PDR2. |
| 2      | P22      | 0             | R/W |                                                                                                                                                                                                   |
| 1      | P21      | 0             | R/W |                                                                                                                                                                                                   |
| 0      | P20      | 0             | R/W |                                                                                                                                                                                                   |

### 9.2.3 Port Mode Register 3 (PMR3)

PMR3 selects the CMOS output or NMOS open-drain output for port 2.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                 |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 5 | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                                                                                                                |
| 4      | POF24    | 0             | R/W | When the bit is set to 1, the corresponding pin is cut off by PMOS and it functions as the NMOS open-drain output. When cleared to 0, the pin functions as the CMOS output. |
| 3      | POF23    | 0             | R/W |                                                                                                                                                                             |
| 2 to 0 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                |

### 9.2.4 Pin Functions

The correspondence between the register specification and the port functions is shown below.

#### P24 pin

| Register      | PCR2  |                |
|---------------|-------|----------------|
| Bit Name      | PCR24 | Pin Function   |
| Setting Value | 0     | P24 input pin  |
|               | 1     | P24 output pin |

## P23 pin

| Register      | PCR2  |                |
|---------------|-------|----------------|
| Bit Name      | PCR23 | Pin Function   |
| Setting Value | 0     | P23 input pin  |
|               | 1     | P23 output pin |

## P22/TXD pin

| Register      | PMR1 | PCR2  |                |
|---------------|------|-------|----------------|
| Bit Name      | TXD  | PCR22 | Pin Function   |
| Setting Value | 0    | 0     | P22 input pin  |
|               |      | 1     | P22 output pin |
|               | 1    | X     | TXD output pin |

Legend X: Don't care.

## P21/RXD pin

| Register      | SCR3 | PCR2  |                |
|---------------|------|-------|----------------|
| Bit Name      | RE   | PCR21 | Pin Function   |
| Setting Value | 0    | 0     | P21 input pin  |
|               |      | 1     | P21 output pin |
|               | 1    | X     | RXD input pin  |

Legend X: Don't care.

## P20/SCK3 pin

| Register      | SCR3 |      | SMR | PCR2  |                 |
|---------------|------|------|-----|-------|-----------------|
| Bit Name      | CKE1 | CKE0 | COM | PCR20 | Pin Function    |
| Setting Value | 0    | 0    | 0   | 0     | P20 input pin   |
|               |      |      |     | 1     | P20 output pin  |
|               | 0    | 0    | 1   | X     | SCK3 output pin |
|               | 0    | 1    | X   | X     | SCK3 output pin |
|               | 1    | X    | X   | X     | SCK3 input pin  |

Legend X: Don't care.

## 9.3 Port 3

Port 3 is a general I/O port. Each pin of the port 3 is shown in figure 9.3.

**Figure 9.3 Port 3 Pin Configuration**

Port 3 has the following registers.

- Port control register 3 (PCR3)
- Port data register 3 (PDR3)

### 9.3.1 Port Control Register 3 (PCR3)

PCR3 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 3.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                  |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------|
| 7   | PCR37    | 0             | W   | Setting a PCR3 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port. |
| 6   | PCR36    | 0             | W   |                                                                                                                              |
| 5   | PCR35    | 0             | W   |                                                                                                                              |
| 4   | PCR34    | 0             | W   |                                                                                                                              |
| 3   | PCR33    | 0             | W   |                                                                                                                              |
| 2   | PCR32    | 0             | W   |                                                                                                                              |
| 1   | PCR31    | 0             | W   |                                                                                                                              |
| 0   | PCR30    | 0             | W   |                                                                                                                              |

### 9.3.2 Port Data Register 3 (PDR3)

PDR3 is a general I/O port data register of port 3.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                   |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | P37      | 0             | R/W | PDR3 stores output data for port 3 pins.<br>If PDR3 is read while PCR3 bits are set to 1, the value stored in PDR3 is read. If PDR3 is read while PCR3 bits are cleared to 0, the pin states are read regardless of the value stored in PDR3. |
| 6   | P36      | 0             | R/W |                                                                                                                                                                                                                                               |
| 5   | P35      | 0             | R/W |                                                                                                                                                                                                                                               |
| 4   | P34      | 0             | R/W |                                                                                                                                                                                                                                               |
| 3   | P33      | 0             | R/W |                                                                                                                                                                                                                                               |
| 2   | P32      | 0             | R/W |                                                                                                                                                                                                                                               |
| 1   | P31      | 0             | R/W |                                                                                                                                                                                                                                               |
| 0   | P30      | 0             | R/W |                                                                                                                                                                                                                                               |

### 9.3.3 Pin Functions

The correspondence between the register specification and the port functions is shown below.

#### P37 pin

| Register      | PCR3  |                |
|---------------|-------|----------------|
| Bit Name      | PCR37 | Pin Function   |
| Setting Value | 0     | P37 input pin  |
|               | 1     | P37 output pin |

#### P36 pin

| Register      | PCR3  |                |
|---------------|-------|----------------|
| Bit Name      | PCR36 | Pin Function   |
| Setting Value | 0     | P36 input pin  |
|               | 1     | P36 output pin |

### P35 pin

| Register      |       | PCR3           |
|---------------|-------|----------------|
| Bit Name      | PCR35 | Pin Function   |
| Setting Value | 0     | P35 input pin  |
|               | 1     | P35 output pin |

### P34 pin

| Register      |       | PCR3           |
|---------------|-------|----------------|
| Bit Name      | PCR34 | Pin Function   |
| Setting Value | 0     | P34 input pin  |
|               | 1     | P34 output pin |

### P33 pin

| Register      |       | PCR3           |
|---------------|-------|----------------|
| Bit Name      | PCR33 | Pin Function   |
| Setting Value | 0     | P33 input pin  |
|               | 1     | P33 output pin |

### P32 pin

| Register      |       | PCR3           |
|---------------|-------|----------------|
| Bit Name      | PCR32 | Pin Function   |
| Setting Value | 0     | P32 input pin  |
|               | 1     | P32 output pin |

### P31 pin

| Register      |       | PCR3           |
|---------------|-------|----------------|
| Bit Name      | PCR31 | Pin Function   |
| Setting Value | 0     | P31 input pin  |
|               | 1     | P31 output pin |

## P30 pin

| Register      | PCR3  |                |
|---------------|-------|----------------|
| Bit Name      | PCR30 | Pin Function   |
| Setting Value | 0     | P30 input pin  |
|               | 1     | P30 output pin |

## 9.4 Port 5

Port 5 is a general I/O port also functioning as an I<sup>2</sup>C bus interface I/O pin, an A/D trigger input pin, and wakeup interrupt input pin. Each pin of the port 5 is shown in figure 9.4. The register setting of the I<sup>2</sup>C bus interface register has priority for functions of the pins P57/SCL and P56/SDA. Since the output buffer for pins P56 and P57 has the NMOS push-pull structure, it differs from an output buffer with the CMOS structure in the high-level output characteristics (see section 23, Electrical Characteristics).

**Figure 9.4 Port 5 Pin Configuration**

Port 5 has the following registers.

- Port mode register 5 (PMR5)
- Port control register 5 (PCR5)
- Port data register 5 (PDR5)
- Port pull-up control register 5 (PUCR5)

### 9.4.1 Port Mode Register 5 (PMR5)

PMR5 switches the functions of pins in port 5.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                 |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | POF57    | 0             | R/W | When the bit is set to 1, the corresponding pin is cut off by PMOS and it functions as the NMOS open-drain output. When cleared to 0, the pin functions as the CMOS output. |
| 6   | POF56    | 0             | R/W |                                                                                                                                                                             |
| 5   | WKP5     | 0             | R/W | This bit selects the function of pin P55/ $\overline{\text{WKP5}}$ /ADTRG.<br>0: General I/O port<br>1: $\overline{\text{WKP5}}$ /ADTRG input pin                           |
| 4   | WKP4     | 0             | R/W | This bit selects the function of pin P54/ $\overline{\text{WKP4}}$ .<br>0: General I/O port<br>1: $\overline{\text{WKP4}}$ input pin                                        |
| 3   | WKP3     | 0             | R/W | This bit selects the function of pin P53/ $\overline{\text{WKP3}}$ .<br>0: General I/O port<br>1: $\overline{\text{WKP3}}$ input pin                                        |
| 2   | WKP2     | 0             | R/W | This bit selects the function of pin P52/ $\overline{\text{WKP2}}$ .<br>0: General I/O port<br>1: $\overline{\text{WKP2}}$ input pin                                        |
| 1   | WKP1     | 0             | R/W | This bit selects the function of pin P51/ $\overline{\text{WKP1}}$ .<br>0: General I/O port<br>1: $\overline{\text{WKP1}}$ input pin                                        |
| 0   | WKP0     | 0             | R/W | This bit selects the function of pin P50/ $\overline{\text{WKP0}}$ .<br>0: General I/O port<br>1: $\overline{\text{WKP0}}$ input pin                                        |

### 9.4.2 Port Control Register 5 (PCR5)

PCR5 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 5.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                           |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | PCR57    | 0             | W   | When each of the port 5 pins P57 to P50 functions as a general I/O port, setting a PCR5 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port. |
| 6   | PCR56    | 0             | W   |                                                                                                                                                                                                       |
| 5   | PCR55    | 0             | W   |                                                                                                                                                                                                       |
| 4   | PCR54    | 0             | W   |                                                                                                                                                                                                       |
| 3   | PCR53    | 0             | W   | Note: The PCR57 and PCR56 bits should not be set to 1 in the H8/3687N.                                                                                                                                |
| 2   | PCR52    | 0             | W   |                                                                                                                                                                                                       |
| 1   | PCR51    | 0             | W   |                                                                                                                                                                                                       |
| 0   | PCR50    | 0             | W   |                                                                                                                                                                                                       |

### 9.4.3 Port Data Register 5 (PDR5)

PDR5 is a general I/O port data register of port 5.

| Bit | Bit Name | Initial Value | R/W | Description                                                        |
|-----|----------|---------------|-----|--------------------------------------------------------------------|
| 7   | P57      | 0             | R/W | Stores output data for port 5 pins.                                |
| 6   | P56      | 0             | R/W |                                                                    |
| 5   | P55      | 0             | R/W |                                                                    |
| 4   | P54      | 0             | R/W |                                                                    |
| 3   | P53      | 0             | R/W | Note: The P57 and P56 bits should not be set to 1 in the H8/3687N. |
| 2   | P52      | 0             | R/W |                                                                    |
| 1   | P51      | 0             | R/W |                                                                    |
| 0   | P50      | 0             | R/W |                                                                    |

#### 9.4.4 Port Pull-Up Control Register 5 (PUCR5)

PUCR5 controls the pull-up MOS in bit units of the pins set as the input ports.

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                |
|------|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7, 6 | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                                                                                                                                               |
| 5    | PUCR55   | 0             | R/W | Only bits for which PCR5 is cleared are valid. The pull-up MOS of the corresponding pins enter the on-state when these bits are set to 1, while they enter the off-state when these bits are cleared to 0. |
| 4    | PUCR54   | 0             | R/W |                                                                                                                                                                                                            |
| 3    | PUCR53   | 0             | R/W |                                                                                                                                                                                                            |
| 2    | PUCR52   | 0             | R/W |                                                                                                                                                                                                            |
| 1    | PUCR51   | 0             | R/W |                                                                                                                                                                                                            |
| 0    | PUCR50   | 0             | R/W |                                                                                                                                                                                                            |

#### 9.4.5 Pin Functions

The correspondence between the register specification and the port functions is shown below.

##### P57/SCL pin

| Register      | ICCR1 | PCR5  |                |
|---------------|-------|-------|----------------|
| Bit Name      | ICE   | PCR57 | Pin Function   |
| Setting Value | 0     | 0     | P57 input pin  |
|               |       | 1     | P57 output pin |
|               | 1     | X     | SCL I/O pin    |

Legend X: Don't care.

SCL performs the NMOS open-drain output, that enables a direct bus drive.

##### P56/SDA pin

| Register      | ICCR1 | PCR5  |                |
|---------------|-------|-------|----------------|
| Bit Name      | ICE   | PCR56 | Pin Function   |
| Setting Value | 0     | 0     | P56 input pin  |
|               |       | 1     | P56 output pin |
|               | 1     | X     | SDA I/O pin    |

Legend X: Don't care.

SDA performs the NMOS open-drain output, that enables a direct bus drive.

### P55/ $\overline{\text{WKP5}}$ / $\overline{\text{ADTRG}}$ pin

| Register      | PMR5 | PCR5  |                                          |
|---------------|------|-------|------------------------------------------|
| Bit Name      | WKP5 | PCR55 | Pin Function                             |
| Setting Value | 0    | 0     | P55 input pin                            |
|               |      | 1     | P55 output pin                           |
|               | 1    | X     | $\overline{\text{WKP5/ADTRG}}$ input pin |

Legend X: Don't care.

### P54/ $\overline{\text{WKP4}}$ pin

| Register      | PMR5 | PCR5  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | WKP4 | PCR54 | Pin Function                       |
| Setting Value | 0    | 0     | P54 input pin                      |
|               |      | 1     | P54 output pin                     |
|               | 1    | X     | $\overline{\text{WKP4}}$ input pin |

Legend X: Don't care.

### P53/ $\overline{\text{WKP3}}$ pin

| Register      | PMR5 | PCR5  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | WKP3 | PCR53 | Pin Function                       |
| Setting Value | 0    | 0     | P53 input pin                      |
|               |      | 1     | P53 output pin                     |
|               | 1    | X     | $\overline{\text{WKP3}}$ input pin |

Legend X: Don't care.

### P52/ $\overline{\text{WKP2}}$ pin

| Register      | PMR5 | PCR5  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | WKP2 | PCR52 | Pin Function                       |
| Setting Value | 0    | 0     | P52 input pin                      |
|               |      | 1     | P52 output pin                     |
|               | 1    | X     | $\overline{\text{WKP2}}$ input pin |

Legend X: Don't care.

### P51/ $\overline{\text{WKP1}}$ pin

| Register      | PMR5 | PCR5  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | WKP1 | PCR51 | Pin Function                       |
| Setting Value | 0    | 0     | P51 input pin                      |
|               |      | 1     | P51 output pin                     |
|               | 1    | X     | $\overline{\text{WKP1}}$ input pin |

Legend X: Don't care.

### P50/ $\overline{\text{WKP0}}$ pin

| Register      | PMR5 | PCR5  |                                    |
|---------------|------|-------|------------------------------------|
| Bit Name      | WKP0 | PCR50 | Pin Function                       |
| Setting Value | 0    | 0     | P50 input pin                      |
|               |      | 1     | P50 output pin                     |
|               | 1    | X     | $\overline{\text{WKP0}}$ input pin |

Legend X: Don't care.

## 9.5 Port 6

Port 6 is a general I/O port also functioning as a timer Z I/O pin. Each pin of the port 6 is shown in figure 9.5. The register setting of the timer Z has priority for functions of the pins for both uses.

**Figure 9.5 Port 6 Pin Configuration**

Port 6 has the following registers.

- Port control register 6 (PCR6)
- Port data register 6 (PDR6)

### 9.5.1 Port Control Register 6 (PCR6)

PCR6 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 6.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                           |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | PCR67    | 0             | W   | When each of the port 6 pins P67 to P60 functions as a general I/O port, setting a PCR6 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port. |
| 6   | PCR66    | 0             | W   |                                                                                                                                                                                                       |
| 5   | PCR65    | 0             | W   |                                                                                                                                                                                                       |
| 4   | PCR64    | 0             | W   |                                                                                                                                                                                                       |
| 3   | PCR63    | 0             | W   |                                                                                                                                                                                                       |
| 2   | PCR62    | 0             | W   |                                                                                                                                                                                                       |
| 1   | PCR61    | 0             | W   |                                                                                                                                                                                                       |
| 0   | PCR60    | 0             | W   |                                                                                                                                                                                                       |

## 9.5.2 Port Data Register 6 (PDR6)

PDR6 is a general I/O port data register of port 6.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                        |
|-----|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | P67      | 0             | R/W | Stores output data for port 6 pins.                                                                                                                                                                |
| 6   | P66      | 0             | R/W | If PDR6 is read while PCR6 bits are set to 1, the value stored in PDR6 are read. If PDR6 is read while PCR6 bits are cleared to 0, the pin states are read regardless of the value stored in PDR6. |
| 5   | P65      | 0             | R/W |                                                                                                                                                                                                    |

Legend X: Don't care.

## 9.6 Port 7

Port 7 is a general I/O port also functioning as a timer V I/O pin and SCI3\_2 I/O pin. Each pin of the port 7 is shown in figure 9.6. The register settings of the timer V and SCI3\_2 have priority for functions of the pins for both uses.

**Figure 9.6 Port 7 Pin Configuration**

Port 7 has the following registers.

- Port control register 7 (PCR7)
- Port data register 7 (PDR7)

### 9.6.1 Port Control Register 7 (PCR7)

PCR7 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 7.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                          |
|-----|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | —             | —   | When each of the port 7 pins P76 to P74 and P72 to P70 functions as a general I/O port, setting a PCR7 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port. |
| 6   | PCR76    | 0             | W   |                                                                                                                                                                                                                      |
| 5   | PCR75    | 0             | W   |                                                                                                                                                                                                                      |
| 4   | PCR74    | 0             | W   |                                                                                                                                                                                                                      |
| 3   | —        | —             | —   | Bits 7 and 3 are reserved bits.                                                                                                                                                                                      |
| 2   | PCR72    | 0             | W   |                                                                                                                                                                                                                      |
| 1   | PCR71    | 0             | W   |                                                                                                                                                                                                                      |
| 0   | PCR70    | 0             | W   |                                                                                                                                                                                                                      |

### 9.6.2 Port Data Register 7 (PDR7)

PDR7 is a general I/O port data register of port 7.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                        |
|-----|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | 1             | —   | Stores output data for port 7 pins.                                                                                                                                                                |
| 6   | P76      | 0             | R/W | If PDR7 is read while PCR7 bits are set to 1, the value stored in PDR7 are read. If PDR7 is read while PCR7 bits are cleared to 0, the pin states are read regardless of the value stored in PDR7. |
| 5   | P75      | 0             | R/W |                                                                                                                                                                                                    |
| 4   | P74      | 0             | R/W |                                                                                                                                                                                                    |
| 3   | —        | 1             | —   | Bits 7 and 3 are reserved bits. These bits are always read as 1.                                                                                                                                   |
| 2   | P72      | 0             | R/W |                                                                                                                                                                                                    |
| 1   | P71      | 0             | R/W |                                                                                                                                                                                                    |
| 0   | P70      | 0             | R/W |                                                                                                                                                                                                    |

### 9.6.3 Pin Functions

The correspondence between the register specification and the port functions is shown below.

#### P76/TMOV pin

| Register      | TCSR_V                      | PCR7  |                 |
|---------------|-----------------------------|-------|-----------------|
| Bit Name      | OS3 to OS0                  | PCR76 | Pin Function    |
| Setting Value | 0000                        | 0     | P76 input pin   |
|               |                             | 1     | P76 output pin  |
|               | Other than the above values | X     | TMOV output pin |

Legend X: Don't care.

#### P75/TMCIV pin

| Register      | PCR7  |                            |
|---------------|-------|----------------------------|
| Bit Name      | PCR75 | Pin Function               |
| Setting Value | 0     | P75 input/TMCIV input pin  |
|               | 1     | P75 output/TMCIV input pin |

### P74/TMRIV pin

| Register      | PCR7  |                            |
|---------------|-------|----------------------------|
| Bit Name      | PCR74 | Pin Function               |
| Setting Value | 0     | P74 input/TMRIV input pin  |
|               | 1     | P74 output/TMRIV input pin |

### P72/TXD\_2 pin

| Register      | PMR1 | PCR7  |                  |
|---------------|------|-------|------------------|
| Bit Name      | TXD2 | PCR72 | Pin Function     |
| Setting Value | 0    | 0     | P72 input pin    |
|               |      | 1     | P72 output pin   |
|               | 1    | X     | TXD_2 output pin |

Legend X: Don't care.

### P71/RXD\_2 pin

| Register      | SCR3_2 | PCR7  |                 |
|---------------|--------|-------|-----------------|
| Bit Name      | RE     | PCR71 | Pin Function    |
| Setting Value | 0      | 0     | P71 input pin   |
|               |        | 1     | P71 output pin  |
|               | 1      | X     | RXD_2 input pin |

Legend X: Don't care.

### P70/SCK3\_2 pin

| Register      | SCR3_2 |      | SMR2 | PCR7  |                   |
|---------------|--------|------|------|-------|-------------------|
| Bit Name      | CKE1   | CKE0 | COM  | PCR70 | Pin Function      |
| Setting Value | 0      | 0    | 0    | 0     | P70 input pin     |
|               |        |      |      | 1     | P70 output pin    |
|               | 0      | 0    | 1    | X     | SCK3_2 output pin |
|               | 0      | 1    | X    | X     | SCK3_2 output pin |
|               | 1      | X    | X    | X     | SCK3_2 input pin  |

Legend X: Don't care.

## 9.7 Port 8

Port 8 is a general I/O port. Each pin of the port 8 is shown in figure 9.7.

**Figure 9.7 Port 8 Pin Configuration**

Port 8 has the following registers.

- Port control register 8 (PCR8)
- Port data register 8 (PDR8)

### 9.7.1 Port Control Register 8 (PCR8)

PCR8 selects inputs/outputs in bit units for pins to be used as general I/O ports of port 8.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                           |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | PCR87    | 0             | W   | When each of the port 8 pins P87 to P85 functions as a general I/O port, setting a PCR8 bit to 1 makes the corresponding pin an output port, while clearing the bit to 0 makes the pin an input port. |
| 6      | PCR86    | 0             | W   |                                                                                                                                                                                                       |
| 5      | PCR85    | 0             | W   |                                                                                                                                                                                                       |
| 4 to 0 | —        | —             | —   | Reserved                                                                                                                                                                                              |

### 9.7.2 Port Data Register 8 (PDR8)

PDR8 is a general I/O port data register of port 8.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                       |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | P87      | 0             | R/W | PDR8 stores output data for port 8 pins.                                                                                                                                                          |
| 6      | P86      | 0             | R/W | If PDR8 is read while PCR8 bits are set to 1, the value stored in PDR8 is read. If PDR8 is read while PCR8 bits are cleared to 0, the pin states are read regardless of the value stored in PDR8. |
| 5      | P85      | 0             | R/W |                                                                                                                                                                                                   |
| 4 to 0 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                      |

### 9.7.3 Pin Functions

The correspondence between the register specification and the port functions is shown below.

#### P87 pin

| Register      | PCR8  |                |
|---------------|-------|----------------|
| Bit Name      | PCR87 | Pin Function   |
| Setting Value | 0     | P87 input pin  |
|               | 1     | P87 output pin |

#### P86 pin

| Register      | PCR8  |                |
|---------------|-------|----------------|
| Bit Name      | PCR86 | Pin Function   |
| Setting Value | 0     | P86 input pin  |
|               | 1     | P86 output pin |

#### P85 pin

| Register      | PCR8  |                |
|---------------|-------|----------------|
| Bit Name      | PCR85 | Pin Function   |
| Setting Value | 0     | P85 input pin  |
|               | 1     | P85 output pin |

## 9.8 Port B

Port B is an input port also functioning as an A/D converter analog input pin. Each pin of the port B is shown in figure 9.8.

**Figure 9.8 Port B Pin Configuration**

Port B has the following register.

- Port data register B (PDRB)

### 9.8.1 Port Data Register B (PDRB)

PDRB is a general input-only port data register of port B.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                             |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------|
| 7   | PB7      | —             | R   | The input value of each pin is read by reading this register.                                           |
| 6   | PB6      | —             | R   |                                                                                                         |
| 5   | PB5      | —             | R   | However, if a port B pin is designated as an analog input channel by ADCSR in A/D converter, 0 is read. |

## Section 10 Realtime Clock (RTC)

The realtime clock (RTC) is a timer used to count time ranging from a second to a week. Figure 10.1 shows the block diagram of the RTC.

### 10.1 Features

- Counts seconds, minutes, hours, and day-of-week
- Start/stop function
- Reset function
- Readable/writable counter of seconds, minutes, hours, and day-of-week with BCD codes
- Periodic (seconds, minutes, hours, days, and weeks) interrupts
- 8-bit free running counter
- Selection of clock source

#### Legend

| PSS:    | Prescaler S                                             |

**Figure 10.1 Block Diagram of RTC**

## 10.2 Input/Output Pin

Table 10.1 shows the RTC input/output pin.

**Table 10.1 Pin Configuration**

| Name         | Abbreviation | I/O    | Function                 |
|--------------|--------------|--------|--------------------------|
| Clock output | TMOW         | Output | RTC divided clock output |

## 10.3 Register Descriptions

The RTC has the following registers.

- Second data register/free running counter data register (RSECDR)
- Minute data register (RMINDR)
- Hour data register (RHRDR)
- Day-of-week data register (RWKDR)
- RTC control register 1 (RTCCR1)
- RTC control register 2 (RTCCR2)
- Clock source select register (RTCCSR)

### 10.3.1 Second Data Register/Free Running Counter Data Register (RSECDR)

RSECDR counts the BCD-coded second value. The setting range is decimal 00 to 59. It is an 8-bit read register used as a counter, when it operates as a free running counter. For more information on reading seconds, minutes, hours, and day-of-week, see section 10.4.3, Data Reading Procedure.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                           |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | BSY      | —             | R   | RTC busy<br><br>This bit is set to 1 when the RTC is updating (operating) the values of second, minute, hour, and day-of-week data registers. When this bit is 0, the values of second, minute, hour, and day-of-week data registers must be adopted. |
| 6   | SC12     | —             | R/W | Counting ten's position of seconds                                                                                                                                                                                                                    |
| 5   | SC11     | —             | R/W | Counts on 0 to 5 for 60-second counting.                                                                                                                                                                                                              |
| 4   | SC10     | —             | R/W |                                                                                                                                                                                                                                                       |
| 3   | SC03     | —             | R/W | Counting one's position of seconds                                                                                                                                                                                                                    |
| 2   | SC02     | —             | R/W | Counts on 0 to 9 once per second. When a carry is generated, 1 is added to the ten's position.                                                                                                                                                        |
| 1   | SC01     | —             | R/W |                                                                                                                                                                                                                                                       |
| 0   | SC00     | —             | R/W |                                                                                                                                                                                                                                                       |

### 10.3.2 Minute Data Register (RMINDR)

RMINDR counts the BCD-coded minute value on the carry generated once per minute by the RSECDR counting. The setting range is decimal 00 to 59.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                           |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | BSY      | —             | R   | RTC busy<br><br>This bit is set to 1 when the RTC is updating (operating) the values of second, minute, hour, and day-of-week data registers. When this bit is 0, the values of second, minute, hour, and day-of-week data registers must be adopted. |
| 6   | MN12     | —             | R/W | Counting ten's position of minutes                                                                                                                                                                                                                    |
| 5   | MN11     | —             | R/W | Counts on 0 to 5 for 60-minute counting.                                                                                                                                                                                                              |
| 4   | MN10     | —             | R/W |                                                                                                                                                                                                                                                       |
| 3   | MN03     | —             | R/W | Counting one's position of minutes                                                                                                                                                                                                                    |
| 2   | MN02     | —             | R/W | Counts on 0 to 9 once per minute. When a carry is generated, 1 is added to the ten's position.                                                                                                                                                        |
| 1   | MN01     | —             | R/W |                                                                                                                                                                                                                                                       |
| 0   | MN00     | —             | R/W |                                                                                                                                                                                                                                                       |

### 10.3.3 Hour Data Register (RHRDR)

RHRDR counts the BCD-coded hour value on the carry generated once per hour by RMINDR. The setting range is either decimal 00 to 11 or 00 to 23 by the selection of the 12/24 bit in RTCCR1.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                           |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | BSY      | —             | R   | RTC busy<br><br>This bit is set to 1 when the RTC is updating (operating) the values of second, minute, hour, and day-of-week data registers. When this bit is 0, the values of second, minute, hour, and day-of-week data registers must be adopted. |
| 6   | —        | 0             | —   | Reserved<br><br>This bit is always read as 0.                                                                                                                                                                                                         |
| 5   | HR11     | —             | R/W | Counting ten's position of hours                                                                                                                                                                                                                      |
| 4   | HR10     | —             | R/W | Counts on 0 to 2 for ten's position of hours.                                                                                                                                                                                                         |
| 3   | HR03     | —             | R/W | Counting one's position of hours                                                                                                                                                                                                                      |
| 2   | HR02     | —             | R/W | Counts on 0 to 9 once per hour. When a carry is generated, 1 is added to the ten's position.                                                                                                                                                          |
| 1   | HR01     | —             | R/W |                                                                                                                                                                                                                                                       |
| 0   | HR00     | —             | R/W |                                                                                                                                                                                                                                                       |

### 10.3.4 Day-of-Week Data Register (RWKDR)

RWKDR counts the BCD-coded day-of-week value on the carry generated once per day by RHRDR. The setting range is decimal 0 to 6 using bits WK2 to WK0.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                           |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | BSY      | —             | R   | RTC busy<br><br>This bit is set to 1 when the RTC is updating (operating) the values of second, minute, hour, and day-of-week data registers. When this bit is 0, the values of second, minute, hour, and day-of-week data registers must be adopted. |
| 6 to 3 | —        | All 0         | —   | Reserved<br><br>These bits are always read as 0.                                                                                                                                                                                                      |
| 2      | WK2      | —             | R/W | Day-of-week counting                                                                                                                                                                                                                                  |

| 3 to 0 | —        | All 0         | —   | Reserved<br>These bits are always read as 0.                                                                                                         |

**Figure 10.2 Definition of Time Expression**

### 10.3.6 RTC Control Register 2 (RTCCR2)

RTCCR2 controls RTC periodic interrupts of weeks, days, hours, minutes, and seconds. Enabling interrupts of weeks, days, hours, minutes, and seconds sets the IRRTA flag to 1 in the interrupt flag register 1 (IRR1) when an interrupt occurs. It also controls an overflow interrupt of a free running counter when RTC operates as a free running counter.

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                             |

### 10.3.7 Clock Source Select Register (RTCCSR)

RTCCSR selects clock source. A free running counter controls start/stop of counter operation by the RUN bit in RTCCR1. When a clock other than 32.768 kHz is selected, the RTC is disabled and operates as an 8-bit free running counter. When the RTC operates as an 8-bit free running counter, RSECDR enables counter values to be read. An interrupt can be generated by setting 1 to the FOIE bit in RTCCR2 and enabling an overflow interrupt of the free running counter. A clock in which the system clock is divided by 32, 16, 8, or 4 is output in active or sleep mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 10.4 Operation

### 10.4.1 Initial Settings of Registers after Power-On

The RTC registers that store second, minute, hour, and day-of week data are not reset by a  $\overline{\text{RES}}$  input. Therefore, all registers must be set to their initial values after power-on. Once the register setting are made, the RTC provides an accurate time as long as power is supplied regardless of a  $\overline{\text{RES}}$  input.

### 10.4.2 Initial Setting Procedure

Figure 10.3 shows the procedure for the initial setting of the RTC. To set the RTC again, also follow this procedure.

**Figure 10.3 Initial Setting Procedure**

10.4.3 Data Reading Procedure

When the seconds, minutes, hours, or day-of-week datum is updated while time data is being read, the data obtained may not be correct, and so the time data must be read again. Figure 10.4 shows an example in which correct data is not obtained. In this example, since only RSECDR is read after data update, about 1-minute inconsistency occurs.

To avoid reading in this timing, the following processing must be performed.

- 1. Check the setting of the BSY bit, and when the BSY bit changes from 1 to 0, read from the second, minute, hour, and day-of-week registers. When about 62.5 ms is passed after the BSY bit is set to 1, the registers are updated, and the BSY bit is cleared to 0.
- 2. Making use of interrupts, read from the second, minute, hour, and day-of week registers after the IRRTA flag in IRR1 is set to 1 and the BSY bit is confirmed to be 0.
- 3. Read from the second, minute, hour, and day-of week registers twice in a row, and if there is no change in the read data, the read data is used.

Figure 10.4 Example: Reading of Inaccurate Time Data

## 10.5 Interrupt Source

There are five kinds of RTC interrupts: week interrupts, day interrupts, hour interrupts, minute interrupts, and second interrupts.

When using an interrupt, initiate the RTC last after other registers are set. Do not set multiple interrupt enable bits in RTCCR2 simultaneously to 1.

When an interrupt request of the RTC occurs, the IRRTA flag in IRR1 is set to 1. When clearing the flag, write 0.

**Table 10.2 Interrupt Source**

| Interrupt Name            | Interrupt Source                                                      | Interrupt Enable Bit |
|---------------------------|-----------------------------------------------------------------------|----------------------|
| Overflow interrupt        | Occurs when the free running counter is overflowed.                   | FOIE                 |
| Week periodic interrupt   | Occurs every week when the day-of-week date register value becomes 0. | WKIE                 |
| Day periodic interrupt    | Occurs every day when the day-of-week date register is counted.       | DYIE                 |
| Hour periodic interrupt   | Occurs every hour when the hour date register is counted.             | HRIE                 |
| Minute periodic interrupt | Occurs every minute when the minute date register is counted.         | MNIE                 |
| Second periodic interrupt | Occurs every second when the second date register is counted.         | SCIE                 |

# Section 11 Timer B1

Timer B1 is an 8-bit timer that increments each time a clock pulse is input. This timer has two operating modes, interval and auto reload. Figure 11.1 shows a block diagram of timer B1.

## 11.1 Features

- Selection of seven internal clock sources ( $\phi/8192$ ,  $\phi/2048$ ,  $\phi/512$ ,  $\phi/256$ ,  $\phi/64$ ,  $\phi/16$ , and  $\phi/4$ ) or an external clock (can be used to count external events).
- An interrupt is generated when the counter overflows.

**Figure 11.1 Block Diagram of Timer B1**

## 11.2 Input/Output Pin

Table 11.1 shows the timer B1 pin configuration.

**Table 11.1 Pin Configuration**

| Name                 | Abbreviation | I/O   | Function            |
|----------------------|--------------|-------|---------------------|
| Timer B1 event input | TMIB1        | Input | Event input to TCB1 |

## 11.3 Register Descriptions

The timer B1 has the following registers.

- Timer mode register B1 (TMB1)
- Timer counter B1 (TCB1)
- Timer load register B1 (TLB1)

### 11.3.1 Timer Mode Register B1 (TMB1)

TMB1 selects the auto-reload function and input clock.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 6 to 3 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2      | TMB12    | 0             | R/W | Clock select                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1      | TMB11    | 0             | R/W | 000: Internal clock: $\phi/8192$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0      | TMB10    | 0             | R/W | 001: Internal clock: $\phi/2048$<br>010: Internal clock: $\phi/512$<br>011: Internal clock: $\phi/256$<br>100: Internal clock: $\phi/64$<br>101: Internal clock: $\phi/16$<br>110: Internal clock: $\phi/4$<br>111: External event (TMIB1): rising or falling edge*<br>Note: * The edge of the external event signal is selected by bit IEG1 in the interrupt edge select register 1 (IEGR1). See section 3.2.1, Interrupt Edge Select Register 1 (IEGR1), for details. Before setting TMB12 to TMB10 to 1, IRQ1 in the port mode register 1 (PMR1) should be set to 1. |

### 11.3.2 Timer Counter B1 (TCB1)

TCB1 is an 8-bit read-only up-counter, which is incremented by internal clock input. The clock source for input to this counter is selected by bits TMB12 to TMB10 in TMB1. TCB1 values can be read by the CPU at any time. When TCB1 overflows from H'FF to H'00 or to the value set in TLB1, the IRRTB1 flag in IRR2 is set to 1. TCB1 is allocated to the same address as TLB1. TCB1 is initialized to H'00.

### 11.3.3 Timer Load Register B1 (TLB1)

TLB1 is an 8-bit write-only register for setting the reload value of TCB1. When a reload value is set in TLB1, the same value is loaded into TCB1 as well, and TCB1 starts counting up from that value. When TCB1 overflows during operation in auto-reload mode, the TLB1 value is loaded into TCB1. Accordingly, overflow periods can be set within the range of 1 to 256 input clocks. TLB1 is allocated to the same address as TCB1. TLB1 is initialized to H'00.

## 11.4 Operation

### 11.4.1 Interval Timer Operation

When bit TMB17 in TMB1 is cleared to 0, timer B1 functions as an 8-bit interval timer. Upon reset, TCB1 is cleared to H'00 and bit TMB17 is cleared to 0, so up-counting and interval timing resume immediately. The operating clock of timer B1 is selected from seven internal clock signals output by prescaler S, or an external clock input at pin TMB1. The selection is made by bits TMB12 to TMB10 in TMB1.

After the count value in TMB1 reaches H'FF, the next clock signal input causes timer B1 to overflow, setting flag IRRTB1 in IRR2 to 1. If IENTB1 in IENR2 is 1, an interrupt is requested to the CPU.

At overflow, TCB1 returns to H'00 and starts counting up again. During interval timer operation (TMB17 = 0), when a value is set in TLB1, the same value is set in TCB1.

### 11.4.2 Auto-Reload Timer Operation

Setting bit TMB17 in TMB1 to 1 causes timer B1 to function as an 8-bit auto-reload timer. When a reload value is set in TLB1, the same value is loaded into TCB1, becoming the value from which TCB1 starts its count. After the count value in TCB1 reaches H'FF, the next clock signal input causes timer B1 to overflow. The TLB1 value is then loaded into TCB1, and the count continues from that value. The overflow period can be set within a range from 1 to 256 input clocks, depending on the TLB1 value.

The clock sources and interrupts in auto-reload mode are the same as in interval mode. In auto-reload mode (TMB17 = 1), when a new value is set in TLB1, the TLB1 value is also loaded into TCB1.

### 11.4.3 Event Counter Operation

Timer B1 can operate as an event counter in which TMIB1 is set to an event input pin. External event counting is selected by setting bits TMB12 to TMB10 in TMB1 to 1. TCB1 counts up at rising or falling edge of an external event signal input at pin TMB1.

When timer B1 is used to count external event input, bit IRQ1 in PMR1 should be set to 1 and IEN1 in IENR1 should be cleared to 0 to disable IRQ1 interrupt requests.

## 11.5 Timer B1 Operating Modes

Table 11.2 shows the timer B1 operating modes.

**Table 11.2 Timer B1 Operating Modes**

| Operating Mode |             | Reset | Active    | Sleep     | Subactive | Subsleep | Standby  |
|----------------|-------------|-------|-----------|-----------|-----------|----------|----------|
| TCB1           | Interval    | Reset | Functions | Functions | Halted    | Halted   | Halted   |
|                | Auto-reload | Reset | Functions | Functions | Halted    | Halted   | Halted   |
| TMB1           |             | Reset | Functions | Retained  | Retained  | Retained | Retained |

# Section 12 Timer V

Timer V is an 8-bit timer based on an 8-bit counter. Timer V counts external events. Compare-match signals with two registers can also be used to reset the counter, request an interrupt, or output a pulse signal with an arbitrary duty cycle. Counting can be initiated by a trigger input at the TRGV pin, enabling pulse output control to be synchronized to the trigger, with an arbitrary delay from the trigger input. Figure 12.1 shows a block diagram of timer V.

## 12.1 Features

- Choice of seven clock signals is available.  
Choice of six internal clock sources ( $\phi/128$ ,  $\phi/64$ ,  $\phi/32$ ,  $\phi/16$ ,  $\phi/8$ ,  $\phi/4$ ) or an external clock.
- Counter can be cleared by compare match A or B, or by an external reset signal. If the count stop function is selected, the counter can be halted when cleared.
- Timer output is controlled by two independent compare match signals, enabling pulse output with an arbitrary duty cycle, PWM output, and other applications.
- Three interrupt sources: compare match A, compare match B, timer overflow
- Counting can be initiated by trigger input at the TRGV pin. The rising edge, falling edge, or both edges of the TRGV input can be selected.

**Figure 12.1 Block Diagram of Timer V**

## 12.2 Input/Output Pins

Table 12.1 shows the timer V pin configuration.

**Table 12.1 Pin Configuration**

| Name                | Abbreviation | I/O    | Function                           |
|---------------------|--------------|--------|------------------------------------|
| Timer V output      | TMOV         | Output | Timer V waveform output            |
| Timer V clock input | TMCIV        | Input  | Clock input to TCNTV               |
| Timer V reset input | TMRIV        | Input  | External input to reset TCNTV      |
| Trigger input       | TRGV         | Input  | Trigger input to initiate counting |

## 12.3 Register Descriptions

Time V has the following registers.

- Timer counter V (TCNTV)
- Timer constant register A (TCORA)
- Timer constant register B (TCORB)
- Timer control register V0 (TCRV0)
- Timer control/status register V (TCSRv)
- Timer control register V1 (TCRV1)

### 12.3.1 Timer Counter V (TCNTV)

TCNTV is an 8-bit up-counter. The clock source is selected by bits CKS2 to CKS0 in timer control register V0 (TCRV0). The TCNTV value can be read and written by the CPU at any time. TCNTV can be cleared by an external reset input signal, or by compare match A or B. The clearing signal is selected by bits CCLR1 and CCLR0 in TCRV0.

When TCNTV overflows, OVF is set to 1 in timer control/status register V (TCSRv).

TCNTV is initialized to H'00.

### 12.3.2 Time Constant Registers A and B (TCORA, TCORB)

TCORA and TCORB have the same function.

TCORA and TCORB are 8-bit read/write registers.

TCORA and TCNTV are compared at all times. When the TCORA and TCNTV contents match, CMFA is set to 1 in TCSRv. If CMIEA is also set to 1 in TCRV0, a CPU interrupt is requested. Note that they must not be compared during the T3 state of a TCORA write cycle.

Timer output from the TMOV pin can be controlled by the identifying signal (compare match A) and the settings of bits OS3 to OS0 in TCSRv.

TCORA and TCORB are initialized to H'FF.

### 12.3.3 Timer Control Register V0 (TCRV0)

TCRV0 selects the input clock signals of TCNTV, specifies the clearing conditions of TCNTV, and controls each interrupt request.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                              |

|       |       | 0     | —     | External clock: counts on falling edge              |
|       |       | 1     | —     | External clock: counts on rising and falling edge   |

### 12.3.4 Timer Control/Status Register V (TCSR\_V)

TCSR\_V indicates the status flag and controls outputs by using a compare match.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                               |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | CMFB     | 0             | R/W | Compare Match Flag B<br>Setting condition:<br>When the TCNTV value matches the TCORB value<br>Clearing condition:<br>After reading CMFB = 1, cleared by writing 0 to CMFB |
| 6   | CMFA     | 0             | R/W | Compare Match Flag A<br>Setting condition:<br>When the TCNTV value matches the TCORA value<br>Clearing condition:<br>After reading CMFA = 1, cleared by writing 0 to CMFA |
| 5   | OVF      | 0             | R/W | Timer Overflow Flag<br>Setting condition:<br>When TCNTV overflows from H'FF to H'00<br>Clearing condition:<br>After reading OVF = 1, cleared by writing 0 to OVF          |
| 4   | —        | 1             | —   | Reserved<br>This bit is always read as 1.                                                                                                                                 |
| 3   | OS3      | 0             | R/W | Output Select 3 and 2                                                                                                                                                     |
| 2   | OS2      | 0             | R/W | These bits select an output method for the TMOV pin by the compare match of TCORB and TCNTV.<br>00: No change<br>01: 0 output<br>10: 1 output<br>11: Output toggles       |
| 1   | OS1      | 0             | R/W | Output Select 1 and 0                                                                                                                                                     |
| 0   | OS0      | 0             | R/W | These bits select an output method for the TMOV pin by the compare match of TCORA and TCNTV.<br>00: No change<br>01: 0 output<br>10: 1 output<br>11: Output toggles       |

OS3 and OS2 select the output level for compare match B. OS1 and OS0 select the output level for compare match A. The two output levels can be controlled independently. After a reset, the timer output is 0 until the first compare match.

### 12.3.5 Timer Control Register V1 (TCRV1)

TCRV1 selects the edge at the TRGV pin, enables TRGV input, and selects the clock input to TCNTV.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                         |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 5 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                                                                                                                                                                                                                                        |

## 12.4 Operation

### 12.4.1 Timer V Operation

1. According to table 12.2, six internal/external clock signals output by prescaler S can be selected as the timer V operating clock signals. When the operating clock signal is selected, TCNTV starts counting-up. Figure 12.2 shows the count timing with an internal clock signal selected, and figure 12.3 shows the count timing with both edges of an external clock signal selected.
2. When TCNTV overflows (changes from H'FF to H'00), the overflow flag (OVF) in TCRV0 will be set. The timing at this time is shown in figure 12.4. An interrupt request is sent to the CPU when OVIE in TCRV0 is 1.
3. TCNTV is constantly compared with TCORA and TCORB. Compare match flag A or B (CMFA or CMFB) is set to 1 when TCNTV matches TCORA or TCORB, respectively. The compare-match signal is generated in the last state in which the values match. Figure 12.5 shows the timing. An interrupt request is generated for the CPU when CMIEA or CMIEB in TCRV0 is 1.
4. When a compare match A or B is generated, the TMOV responds with the output value selected by bits OS3 to OS0 in TCSR.V. Figure 12.6 shows the timing when the output is toggled by compare match A.
5. When CCLR1 or CCLR0 in TCRV0 is 01 or 10, TCNTV can be cleared by the corresponding compare match. Figure 12.7 shows the timing.
6. When CCLR1 or CCLR0 in TCRV0 is 11, TCNTV can be cleared by the rising edge of the input of TMRIV pin. A TMRIV input pulse-width of at least 1.5 system clocks is necessary. Figure 12.8 shows the timing.
7. When a counter-clearing source is generated with TRGE in TCRV1 set to 1, the counting-up is halted as soon as TCNTV is cleared. TCNTV resumes counting-up when the edge selected by TVEG1 or TVEG0 in TCRV1 is input from the TGRV pin.

## 12.5 Timer V Application Examples

### 12.5.1 Pulse Output with Arbitrary Duty Cycle

Figure 12.9 shows an example of output of pulses with an arbitrary duty cycle.

1. Set bits CCLR1 and CCLR0 in TCRV0 so that TCNTV will be cleared by compare match with TCORA.
2. Set bits OS3 to OS0 in TCSR0 so that the output will go to 1 at compare match with TCORA and to 0 at compare match with TCORB.
3. Set bits CKS2 to CKS0 in TCRV0 and bit ICKS0 in TCRV1 to select the desired clock source.
4. With these settings, a waveform is output without further software intervention, with a period determined by TCORA and a pulse width determined by TCORB.

**Figure 12.9 Pulse Output Example**

### 12.5.2 Pulse Output with Arbitrary Pulse Width and Delay from TRGV Input

The trigger function can be used to output a pulse with an arbitrary pulse width at an arbitrary delay from the TRGV input, as shown in figure 12.10. To set up this output:

1. Set bits CCLR1 and CCLR0 in TCRV0 so that TCNTV will be cleared by compare match with TCORB.
2. Set bits OS3 to OS0 in TCSR0 so that the output will go to 1 at compare match with TCORA and to 0 at compare match with TCORB.
3. Set bits TVEG1 and TVEG0 in TCRV1 and set TRGE to select the falling edge of the TRGV input.
4. Set bits CKS2 to CKS0 in TCRV0 and bit ICKS0 in TCRV1 to select the desired clock source.
5. After these settings, a pulse waveform will be output without further software intervention, with a delay determined by TCORA from the TRGV input, and a pulse width determined by (TCORB – TCORA).

**Figure 12.10 Example of Pulse Output Synchronized to TRGV Input**

## 12.6 Usage Notes

The following types of contention or operation can occur in timer V operation.

1. Writing to registers is performed in the T3 state of a TCNTV write cycle. If a TCNTV clear signal is generated in the T3 state of a TCNTV write cycle, as shown in figure 12.11, clearing takes precedence and the write to the counter is not carried out. If counting-up is generated in the T3 state of a TCNTV write cycle, writing takes precedence.
2. If a compare match is generated in the T3 state of a TCORA or TCORB write cycle, the write to TCORA or TCORB takes precedence and the compare match signal is inhibited. Figure 12.12 shows the timing.
3. If compare matches A and B occur simultaneously, any conflict between the output selections for compare match A and compare match B is resolved by the following priority: toggle output > output 1 > output 0.
4. Depending on the timing, TCNTV may be incremented by a switch between different internal clock sources. When TCNTV is internally clocked, an increment pulse is generated from the falling edge of an internal clock signal, that is divided system clock ( $\phi$ ). Therefore, as shown in figure 12.3 the switch is from a high clock signal to a low clock signal, the switchover is seen as a falling edge, causing TCNTV to increment. TCNTV can also be incremented by a switch between internal and external clocks.

# Section 13 Timer Z

The timer Z has a 16-bit timer with two channels. Figures 13.1, 13.2, and 13.3 show the block diagrams of entire timer Z, its channel 0, and its channel 1, respectively. For details on the timer Z functions, refer to table 13.1.

## 13.1 Features

- Capability to process up to eight inputs/outputs
- Eight general registers (GR): four registers for each channel
  - Independently assignable output compare or input capture functions
- Selection of five counter clock sources: four internal clocks ( $\phi$ ,  $\phi/2$ ,  $\phi/4$ , and  $\phi/8$ ) and an external clock
- Seven selectable operating modes
  - Output compare function
    - Selection of 0 output, 1 output, or toggle output
  - Input capture function
    - Rising edge, falling edge, or both edges
  - Synchronous operation
    - Timer counters\_0 and \_1 (TCNT\_0 and TCNT\_1) can be written simultaneously.
    - Simultaneous clearing by compare match or input capture is possible.
  - PWM mode
    - Up to six-phase PWM output can be provided with desired duty ratio.
  - Reset synchronous PWM mode
    - Three-phase PWM output for normal and counter phases
  - Complementary PWM mode
    - Three-phase PWM output for non-overlapped normal and counter phases
    - The A/D conversion start trigger can be set for PWM cycles.
  - Buffer operation
    - The input capture register can be consisted of double buffers.
    - The output compare register can automatically be modified.
- High-speed access by the internal 16-bit bus
  - 16-bit TCNT and GR registers can be accessed in high speed by a 16-bit bus interface
- Any initial timer output value can be set
- Output of the timer is disabled by external trigger
- Eleven interrupt sources
  - Four compare match/input capture interrupts and an overflow interrupt are available for each channel. An underflow interrupt can be set for channel 1.

**Table 13.1 Timer Z Functions**

| Item                                                          |          | Channel 0                                                                                 | Channel 1                                                     |

## 13.2 Input/Output Pins

Table 13.2 summarizes the timer Z pins.

**Table 13.2 Pin Configuration**

| Name                            | Abbreviation | Input/Output | Function                                                                                                                                 |
|---------------------------------|--------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Input capture/output compare A0 | FTIOA0       | Input/output | GRA_0 output compare output, GRA_0 input capture input, or external clock input (TCLK)                                                   |
| Input capture/output compare B0 | FTIOB0       | Input/output | GRB_0 output compare output, GRB_0 input capture input, or PWM output                                                                    |
| Input capture/output compare C0 | FTIOC0       | Input/output | GRC_0 output compare output, GRC_0 input capture input, or PWM synchronous output (in reset synchronous PWM and complementary PWM modes) |
| Input capture/output compare D0 | FTIOD0       | Input/output | GRD_0 output compare output, GRD_0 input capture input, or PWM output                                                                    |
| Input capture/output compare A1 | FTIOA1       | Input/output | GRA_1 output compare output, GRA_1 input capture input, or PWM output (in reset synchronous PWM and complementary PWM modes)             |
| Input capture/output compare B1 | FTIOB1       | Input/output | GRB_1 output compare output, GRB_1 input capture input, or PWM output                                                                    |
| Input capture/output compare C1 | FTIOC1       | Input/output | GRC_1 output compare output, GRC_1 input capture input, or PWM output                                                                    |
| Input capture/output compare D1 | FTIOD1       | Input/output | GRD_1 output compare output, GRD_1 input capture input, or PWM output                                                                    |

## 13.3 Register Descriptions

The timer Z has the following registers.

### Common

- Timer start register (TSTR)
- Timer mode register (TMDR)
- Timer PWM mode register (TPMR)
- Timer function control register (TFCR)
- Timer output master enable register (TOER)
- Timer output control register (TOCR)

### Channel 0

- Timer control register\_0 (TCR\_0)
- Timer I/O control register A\_0 (TIORA\_0)
- Timer I/O control register C\_0 (TIORC\_0)
- Timer status register\_0 (TSR\_0)
- Timer interrupt enable register\_0 (TIER\_0)
- PWM mode output level control register\_0 (POCR\_0)
- Timer counter\_0 (TCNT\_0)
- General register A\_0 (GRA\_0)
- General register B\_0 (GRB\_0)
- General register C\_0 (GRC\_0)
- General register D\_0 (GRD\_0)

### Channel 1

- Timer control register\_1 (TCR\_1)
- Timer I/O control register A\_1 (TIORA\_1)
- Timer I/O control register C\_1 (TIORC\_1)
- Timer status register\_1 (TSR\_1)
- Timer interrupt enable register\_1 (TIER\_1)
- PWM mode output level control register\_1 (POCR\_1)
- Timer counter\_1 (TCNT\_1)
- General register A\_1 (GRA\_1)
- General register B\_1 (GRB\_1)
- General register C\_1 (GRC\_1)
- General register D\_1 (GRD\_1)

### 13.3.1 Timer Start Register (TSTR)

TSTR selects the operation/stop for the TCNT counter.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                      |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 7 to 2 | —        | All 1         | —   | Reserved<br>These bits are always read as 1, and cannot be modified.             |
| 1      | STR1     | 0             | R/W | Channel 1 Counter Start<br>0: TCNT_1 halts counting<br>1: TCNT_1 starts counting |
| 0      | STR0     | 0             | R/W | Channel 0 Counter Start<br>0: TCNT_0 halts counting<br>1: TCNT_0 starts counting |

### 13.3.2 Timer Mode Register (TMDR)

TMDR selects buffer operation settings and synchronized operation.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                    |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------|
| 7      | BFD1     | 0             | R/W | Buffer Operation D1<br>0: GRD_1 operates normally<br>1: GRB_1 and GRD_1 are used together for buffer operation |
| 6      | BFC1     | 0             | R/W | Buffer Operation C1<br>0: GRC_1 operates normally<br>1: GRA_1 and GRD_1 are used together for buffer operation |
| 5      | BFD0     | 0             | R/W | Buffer Operation D0<br>0: GRD_0 operates normally<br>1: GRB_0 and GRD_0 are used together for buffer operation |
| 4      | BFC0     | 0             | R/W | Buffer Operation C0<br>0: GRC_0 operates normally<br>1: GRA_0 and GRC_0 are used together for buffer operation |
| 3 to 1 | —        | All 1         | —   | Reserved<br>These bits are always read as 1, and cannot be modified.                                           |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                               |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | SYNC     | 0             | R/W | Timer Synchronization<br>0: TCNT_1 and TCNT_0 operate independently<br>1: TCNT_1 and TCNT_0 are synchronized<br>TCNT_1 and TCNT_0 can be pre-set or cleared synchronously |

### 13.3.3 Timer PWM Mode Register (TPMR)

TPMR sets the pin to enter PWM mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                  |
|-----|----------|---------------|-----|------------------------------------------------------------------------------|
| 7   | —        | 1             | —   | Reserved<br>This bit is always read as 1, and cannot be modified.            |
| 6   | PWMD1    | 0             | R/W | PWM Mode D1<br>0: FTIOD1 operates normally<br>1: FTIOD1 operates in PWM mode |
| 5   | PWMC1    | 0             | R/W | PWM Mode C1<br>0: FTIOC1 operates normally<br>1: FTIOC1 operates in PWM mode |
| 4   | PWMB1    | 0             | R/W | PWM Mode B1<br>0: FTIOB1 operates normally<br>1: FTIOB1 operates in PWM mode |
| 3   | —        | 1             | —   | Reserved<br>This bit is always read as 1, and cannot be modified.            |
| 2   | PWMD0    | 0             | R/W | PWM Mode D0<br>0: FTIOD0 operates normally<br>1: FTIOD0 operates in PWM mode |
| 1   | PWMC0    | 0             | R/W | PWM Mode C0<br>0: FTIOC0 operates normally<br>1: FTIOC0 operates in PWM mode |
| 0   | PWMB0    | 0             | R/W | PWM Mode B0<br>0: FTIOB0 operates normally<br>1: FTIOB0 operates in PWM mode |

### 13.3.4 Timer Function Control Register (TFCR)

TFCR selects the settings and output levels for each operating mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | 1             | —   | Reserved<br>This bit is always read as 1.                                                                                                                                                                                                                                                                                                                                    |
| 6   | STCLK    | 0             | R/W | External Clock Input Select<br>0: External clock input is disabled<br>1: External clock input is enabled                                                                                                                                                                                                                                                                     |
| 5   | ADEG     | 0             | R/W | A/D Trigger Edge Select<br>A/D module should be set to start an A/D conversion by the external trigger<br>0: A/D trigger at the crest in complementary PWM mode<br>1: A/D trigger at the trough in complementary PWM mode                                                                                                                                                    |
| 4   | ADTRG    | 0             | R/W | External Trigger Disable<br>0: A/D trigger for PWM cycles is disabled in complementary PWM mode<br>1: A/D trigger for PWM cycles is enabled in complementary PWM mode                                                                                                                                                                                                        |
| 3   | OLS1     | 0             | R/W | Output Level Select 1<br>Selects the counter-phase output levels in reset synchronous PWM mode or complementary PWM mode.<br>0: Initial output is high and the active level is low.<br>1: Initial output is low and the active level is high.                                                                                                                                |

**Figure 13.4 Example of Outputs in Reset Synchronous PWM Mode and Complementary PWM Mode**

### 13.3.5 Timer Output Master Enable Register (TOER)

TOER enables/disables the outputs for channel 0 and channel 1. When  $\overline{\text{WKP4}}$  is selected for inputs, if a low level signal is input to  $\overline{\text{WKP4}}$ , the bits in TOER are set to 1 to disable the output for timer Z.

### 13.3.6 Timer Output Control Register (TOCR)

TOCR selects the initial outputs before the first occurrence of a compare match. Note that bits OLS1 and OLS0 in TFCR set these initial outputs in reset synchronous PWM mode and complementary PWM mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                |

Note: \* The change of the setting is immediately reflected in the output value.

### 13.3.7 Timer Counter (TCNT)

The timer Z has two TCNT counters (TCNT\_0 and TCNT\_1), one for each channel. The TCNT counters are 16-bit readable/writable registers that increment/decrement according to input clocks. Input clocks can be selected by bits TPSC2 to TPSC0 in TCR. TCNT0 and TCNT 1 increment/decrement in complementary PWM mode, while they only increment in other modes.

The TCNT counters are initialized to H'0000 by compare matches with corresponding GRA, GRB, GRC, or GRD, or input captures to GRA, GRB, GRC, or GRD (counter clearing function). When the TCNT counters overflow, an OVF flag in TSR for the corresponding channel is set to 1. When TCNT\_1 underflows, an UDF flag in TSR is set to 1. The TCNT counters cannot be accessed in 8-bit units; they must always be accessed as a 16-bit unit.

### 13.3.8 General Registers A, B, C, and D (GRA, GRB, GRC, and GRD)

GR are 16-bit registers. Timer Z has eight general registers (GR), four for each channel. The GR registers are dual function 16-bit readable/writable registers, functioning as either output compare or input capture registers. Functions can be switched by TIORA and TIORC.

The values in GR and TCNT are constantly compared with each other when the GR registers are used as output compare registers. When the both values match, the IMFA to IMFD flags in TSR are set to 1. Compare match outputs can be selected by TIORA and TIORC.

When the GR registers are used as input capture registers, the TCNT value is stored after detecting external signals. At this point, IMFA to IMFD flags in the corresponding TSR are set to 1. Detection edges for input capture signals can be selected by TIORA and TIORC.

When PWM mode, complementary PWM mode, or reset synchronous PWM mode is selected, the values in TIORA and TIORC are ignored. Upon reset, the GR registers are set as output compare registers (no output) and initialized to H'FFFF. The GR registers cannot be accessed in 8-bit units; they must always be accessed as a 16-bit unit.

### 13.3.9 Timer Control Register (TCR)

The TCR registers select a TCNT counter clock, an edge when an external clock is selected, and counter clearing sources. Timer Z has a total of two TCR registers, one for each channel.

| Bit | Bit Name | Initial value | R/W | Description                                                                                                             |

- Notes: 1. When GR functions as an output compare register, TCNT is cleared by compare match. When GR functions as input capture, TCNT is cleared by input capture.
2. Synchronous operation is set by TMDR.
3. X: Don't care

### 13.3.10 Timer I/O Control Register (TIOA and TIOB)

The TIOA registers control the general registers (GR). Timer Z has four TIOA registers (TIOA\_0, TIOA\_1, TIOB\_0, and TIOB\_1), two for each channel. In PWM mode including complementary PWM mode and reset synchronous PWM mode, the settings of TIOA are invalid.

**TIOA:** TIOA selects whether GRA or GRB is used as an output compare register or an input capture register. When an output compare register is selected, the output setting is selected. When an input capture register is selected, an input edge of an input capture signal is selected. TIOA also selects the function of FTIOA or FTIOB pin.

**TIORC:** TIORC selects whether GRC or GRD is used as an output compare register or an input capture register. When an output compare register is selected, the output setting is selected. When an input capture register is selected, an input edge of an input capture signal is selected. TIORC also selects the function of FTIOC or FTIOD pin.

### 13.3.11 Timer Status Register (TSR)

TSR indicates generation of an overflow/underflow of TCNT and a compare match/input capture of GRA, GRB, GRC, and GRD. These flags are interrupt sources. If an interrupt is enabled by a corresponding bit in TIER, TSR requests an interrupt for the CPU. Timer Z has two TSR registers, one for each channel.

| Bit  | Bit Name | Initial value | R/W | Description                                                                                                                                                                                                                                 |

Note: Bit 5 is not the UDF flag in TSR\_0. It is a reserved bit. It is always read as 1.

### 13.3.12 Timer Interrupt Enable Register (TIER)

TIER enables or disables interrupt requests for overflow or GR compare match/input capture. Timer Z has two TIER registers, one for each channel.

| Bit    | Bit Name | Initial value | R/W | Description                                                                                                                                                       |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 5 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                                                      |

### 13.3.13 PWM Mode Output Level Control Register (POCR)

POCR control the active level in PWM mode. Timer Z has two POCR registers, one for each channel.

| Bit    | Bit Name | Initial value | R/W | Description                                                                                                                  |
|--------|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------|
| 7 to 3 | —        | All 1         | —   | Reserved<br>These bits are always read as 1.                                                                                 |
| 2      | POLD     | 0             | R/W | PWM Mode Output Level Control D<br>0: The output level of FTIOD is low-active<br>1: The output level of FTIOD is high-active |

| 0      | POLB     | 0             | R/W | PWM Mode Output Level Control B<br>0: The output level of FTIOB is low-active<br>1: The output level of FTIOB is high-active |

### 13.3.14 Interface with CPU

#### 1. 16-bit register

TCNT and GR are 16-bit registers. Reading/writing in a 16-bit unit is enabled but disabled in an 8-bit unit since the data bus with the CPU is 16-bit width. These registers must always be accessed in a 16-bit unit. Figure 13.5 shows an example of accessing the 16-bit registers.

Figure 13.5 Accessing Operation of 16-Bit Register (between CPU and TCNT (16 bits))

## 2. 8-bit register

Registers other than TCNT and GR are 8-bit registers that are connected internally with the CPU in an 8-bit width. Figure 13.6 shows an example of accessing the 8-bit registers.

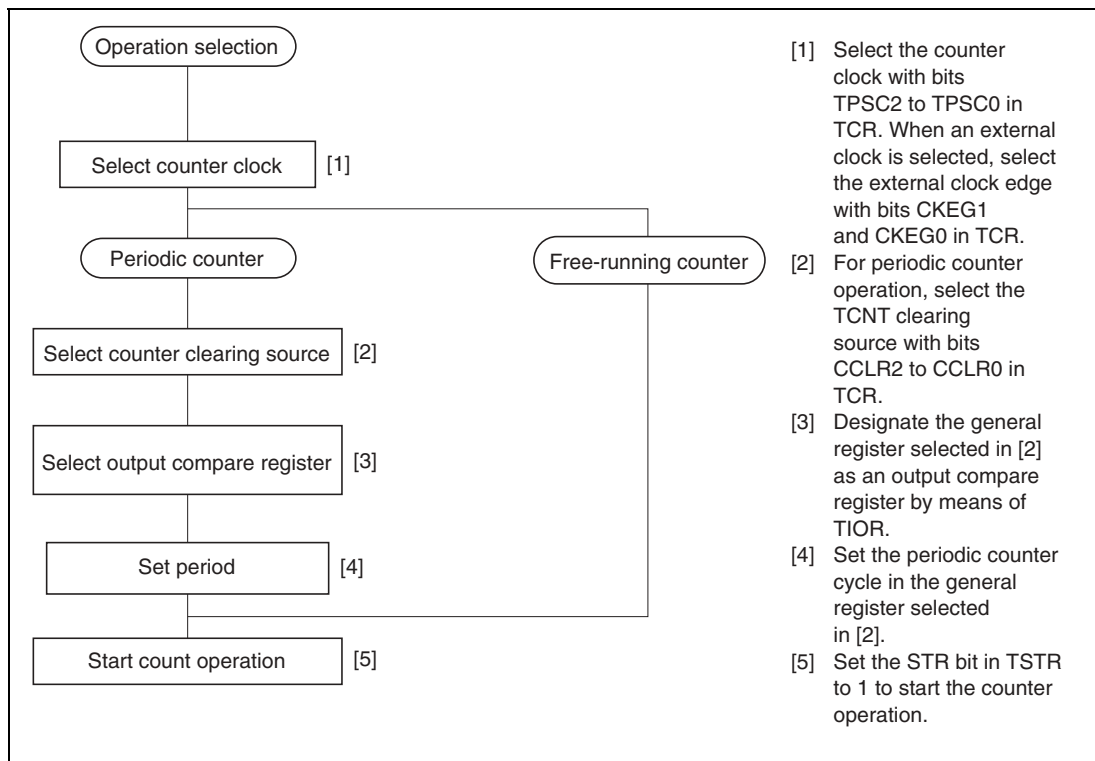

**Figure 13.6 Accessing Operation of 8-Bit Register (between CPU and TSTR (8 bits))**

## 13.4 Operation

### 13.4.1 Counter Operation

When one of bits STR0 and STR1 in TSTR is set to 1, the TCNT counter for the corresponding channel begins counting. TCNT can operate as a free-running counter, periodic counter, for example. Figure 13.7 shows an example of the counter operation setting procedure.

**Figure 13.7 Example of Counter Operation Setting Procedure**

#### 1. Free-running count operation and periodic count operation

Immediately after a reset, the TCNT counters for channels 0 and 1 are all designated as free-running counters. When the relevant bit in TSTR is set to 1, the corresponding TCNT counter starts an increment operation as a free-running counter. When TCNT overflows, the OVF flag in TSR is set to 1. If the value of the OVIE bit in the corresponding TIER is 1 at this point, timer Z requests an interrupt. After overflow, TCNT starts an increment operation again from H'0000.

Figure 13.8 illustrates free-running counter operation.

**Figure 13.8 Free-Running Counter Operation**

When compare match is selected as the TCNT clearing source, the TCNT counter for the relevant channel performs periodic count operation. The GR registers for setting the period are designated as output compare registers, and counter clearing by compare match is selected by means of bits CCLR1 and CCLR0 in TCR. After the settings have been made, TCNT starts an increment operation as a periodic counter when the corresponding bit in TSTR is set to 1. When the count value matches the value in GR, the IMFA, IMFB, IMFC, or IMFD flag in TSR is set to 1 and TCNT is cleared to H'0000.

If the value of the corresponding IMIEA, IMIEB, IMIEC, or IMIED bit in TIER is 1 at this point, the timer Z requests an interrupt. After a compare match, TCNT starts an increment operation again from H'0000.

Figure 13.9 illustrates periodic counter operation.

**Figure 13.9 Periodic Counter Operation**

## 2. TCNT count timing

### A. Internal clock operation

A system clock ( $\phi$ ) or three types of clocks ( $\phi/2$ ,  $\phi/4$ , or  $\phi/8$ ) that divides the system clock can be selected by bits TPSC2 to TPSC0 in TCR.

Figure 13.10 illustrates this timing.

**Figure 13.10 Count Timing at Internal Clock Operation**

### B. External clock operation

An external clock input pin (TCLK) can be selected by bits TPSC2 to TPSC0 in TCR, and a detection edge can be selected by bits CKEG1 and CKEG0. To detect an external clock, the rising edge, falling edge, or both edges can be selected. The pulse width of the external clock needs two or more system clocks. Note that an external clock does not operate correctly with the lower pulse width.

Figure 13.11 illustrates the detection timing of the rising and falling edges.

**Figure 13.11 Count Timing at External Clock Operation (Both Edges Detected)**

### 13.4.2 Waveform Output by Compare Match

Timer Z can perform 0, 1, or toggle output from the corresponding FTIOA, FTIOB, FTIOC, or FTIOD output pin using compare match A, B, C, or D.

Figure 13.12 shows an example of the setting procedure for waveform output by compare match.

**Figure 13.12 Example of Setting Procedure for Waveform Output by Compare Match**

## 1. Examples of waveform output operation

Figure 13.13 shows an example of 0 output/1 output.

In this example, TCNT has been designated as a free-running counter, and settings have been made such that 0 is output by compare match A, and 1 is output by compare match B. When the set level and the pin level coincide, the pin level does not change.

**Figure 13.13 Example of 0 Output/1 Output Operation**

Figure 13.14 shows an example of toggle output.

In this example, TCNT has been designated as a periodic counter (with counter clearing on compare match B), and settings have been made such that the output is toggled by both compare match A and compare match B.

**Figure 13.14 Example of Toggle Output Operation**

## 2. Output compare timing

The compare match signal is generated in the last state in which TCNT and GR match (when TCNT changes from the matching value to the next value). When the compare match signal is generated, the output value selected in TIOR is output at the compare match output pin (FTIOA, FTIOB, FTIOC, or FTIOD). When TCNT matches GR, the compare match signal is generated only after the next TCNT input clock pulse is input.

Figure 13.15 shows an example of the output compare timing.

**Figure 13.15 Output Compare Timing**

### 13.4.3 Input Capture Function

The TCNT value can be transferred to GR on detection of the input edge of the input capture/output compare pin (FTIOA, FTIOB, FTIOC, or FTIOD). Rising edge, falling edge, or both edges can be selected as the detected edge. When the input capture function is used, the pulse width or period can be measured.

Figure 13.16 shows an example of the input capture operation setting procedure.

**Figure 13.16 Example of Input Capture Operation Setting Procedure**

#### 1. Example of input capture operation

Figure 13.17 shows an example of input capture operation.

In this example, both rising and falling edges have been selected as the FTIOA pin input capture input edge, the falling edge has been selected as the FTIOB pin input capture input edge, and counter clearing by GRB input capture has been designated for TCNT.

**Figure 13.17 Example of Input Capture Operation**

## 2. Input capture signal timing

Input capture on the rising edge, falling edge, or both edges can be selected through settings in TIOR. Figure 13.18 shows the timing when the rising edge is selected. The pulse width of the input capture signal must be at least two system clock ( $\phi$ ) cycles.

**Figure 13.18 Input Capture Signal Timing**

### 13.4.4 Synchronous Operation

In synchronous operation, the values in a number of TCNT counters can be rewritten simultaneously (synchronous presetting). Also, a number of TCNT counters can be cleared simultaneously by making the appropriate setting in TCR (synchronous clearing). Synchronous operation enables GR to be increased with respect to a single time base.

Figure 13.19 shows an example of the synchronous operation setting procedure.

**Figure 13.19 Example of Synchronous Operation Setting Procedure**

Figure 13.20 shows an example of synchronous operation. In this example, synchronous operation has been selected, FTIOB0 and FTIOB1 have been designated for PWM mode, GRA\_0 compare match has been set as the channel 0 counter clearing source, and synchronous clearing has been set for the channel 1 counter clearing source. Two-phase PWM waveforms are output from pins FTIOB0 and FTIOB1. At this time, synchronous presetting and synchronous operation by GRA\_0 compare match are performed by TCNT counters.

For details on PWM mode, see section 13.4.5, PWM Mode.

**Figure 13.20 Example of Synchronous Operation**

### 13.4.5 PWM Mode

In PWM mode, PWM waveforms are output from the FTIOB, FTIOC, and FTIOD output pins with GRA as a cycle register and GRB, GRC, and GRD as duty registers. The initial output level of the corresponding pin depends on the setting values of TOCR and POCR. Table 13.3 shows an example of the initial output level of the FTIOB0 pin.

The output level is determined by the POLB to POLD bits corresponding to POCR. When POLB is 0, the FTIOB output pin is set to 0 by compare match B and set to 1 by compare match A. When POLB is 1, the FTIOB output pin is set to 1 by compare match B and cleared to 0 by compare match A. In PWM mode, maximum 6-phase PWM outputs are possible.

Figure 13.21 shows an example of the PWM mode setting procedure.

**Table 13.3 Initial Output Level of FTIOB0 Pin**

| TOB0 | POLB | Initial Output Level |
|------|------|----------------------|
| 0    | 0    | 1                    |
| 0    | 1    | 0                    |
| 1    | 0    | 0                    |
| 1    | 1    | 1                    |

**Figure 13.21 Example of PWM Mode Setting Procedure**

Figure 13.22 shows an example of operation in PWM mode. The output signals go to 1 and TCNT is reset at compare match A, and the output signals go to 0 at compare match B, C, and D (TOB, TOC, and TOD = 0, POLB, POLC, and POLD = 0).

**Figure 13.22 Example of PWM Mode Operation (1)**

Figure 13.23 shows another example of operation in PWM mode. The output signals go to 0 and TCNT is reset at compare match A, and the output signals go to 1 at compare match B, C, and D (TOB, TOC, and TOD = 0, POLB, POLC, and POLD = 1).

**Figure 13.23 Example of PWM Mode Operation (2)**

Figures 13.24 (when TOB, TOC, and TOD = 0, POLB, POLC, and POLD = 0) and 13.25 (when TOB, TOC, and TOD = 0, POLB, POLC, and POLD = 1) show examples of the output of PWM waveforms with duty cycles of 0% and 100% in PWM mode.

**Figure 13.24 Example of PWM Mode Operation (3)**

**Figure 13.25 Example of PWM Mode Operation (4)**

### 13.4.6 Reset Synchronous PWM Mode

Three normal- and counter-phase PWM waveforms are output by combining channels 0 and 1 that one of changing points of waveforms will be common.

In reset synchronous PWM mode, the FTIOB0 to FTIOD0 and FTIOA1 to FTIOD1 pins become PWM-output pins automatically. TCNT\_0 performs an increment operation. Tables 13.4 and 13.5 show the PWM-output pins used and the register settings, respectively.

Figure 13.26 shows the example of reset synchronous PWM mode setting procedure.

**Table 13.4 Output Pins in Reset Synchronous PWM Mode**

| Channel | Pin Name | Input/Output | Pin Function                                          |
|---------|----------|--------------|-------------------------------------------------------|
| 0       | FTIOC0   | Output       | Toggle output in synchronous with PWM cycle           |
| 0       | FTIOB0   | Output       | PWM output 1                                          |
| 0       | FTIOD0   | Output       | PWM output 1 (counter-phase waveform of PWM output 1) |
| 1       | FTIOA1   | Output       | PWM output 2                                          |
| 1       | FTIOC1   | Output       | PWM output 2 (counter-phase waveform of PWM output 2) |
| 1       | FTIOB1   | Output       | PWM output 3                                          |
| 1       | FTIOD1   | Output       | PWM output 3 (counter-phase waveform of PWM output 3) |

**Table 13.5 Register Settings in Reset Synchronous PWM Mode**

| Register | Description                                                                  |
|----------|------------------------------------------------------------------------------|
| TCNT_0   | Initial setting of H'0000                                                    |
| TCNT_1   | Not used (independently operates)                                            |
| GRA_0    | Sets counter cycle of TCNT_0                                                 |
| GRB_0    | Set a changing point of the PWM waveform output from pins FTIOB0 and FTIOD0. |
| GRA_1    | Set a changing point of the PWM waveform output from pins FTIOA1 and FTIOC1. |
| GRB_1    | Set a changing point of the PWM waveform output from pins FTIOB1 and FTIOD1. |

- [1] Clear bit STR0 in TSTR to 0 and stop the counter operation of TCNT\_0. Set reset synchronous PWM mode after TCNT\_0 stops.
- [2] Select the counter clock with bits TPSC2 to TOSC0 in TCR. When an external clock is selected, select the external clock edge with bits CKEG1 and CKEG0 in TCR.
- [3] Use bits CCLR1 and CCLR0 in TCR to select counter clearing source GRA\_0.
- [4] Select the reset synchronous PWM mode with bits CMD1 and CMD0 in TFCR. FTIOB0 to FTIOD0 and FTIOA1 to FTIOD1 become PWM output pins automatically.
- [5] Set H'00 to TOCR.
- [6] Set TCNT\_0 as H'0000. TCNT1 does not need to be set.
- [7] GRA\_0 is a cycle register. Set a cycle for GRA\_0. Set the changing point timing of the PWM output waveform for GRB\_0, GRA\_1, and GRB\_1.
- [8] Enable or disable the timer output by TOER.
- [9] Set the STR bit in TSTR to 1 and start the counter operation.

**Figure 13.26 Example of Reset Synchronous PWM Mode Setting Procedure**

Figures 13.27 and 13.28 show examples of operation in reset synchronous PWM mode.

**Figure 13.27 Example of Reset Synchronous PWM Mode Operation (OLS0 = OLS1 = 1)**

**Figure 13.28 Example of Reset Synchronous PWM Mode Operation (OLS0 = OLS1 = 0)**

In reset synchronous PWM mode, TCNT\_0 and TCNT\_1 perform increment and independent operations, respectively. However, GRA\_1 and GRB\_1 are separated from TCNT\_1. When a compare match occurs between TCNT\_0 and GRA\_0, a counter is cleared and an increment operation is restarted from H'0000.

The PWM pin outputs 0 or 1 whenever a compare match between GRB\_0, GRA\_1, GRB\_1 and TCNT\_0 or counter clearing occur.

For details on operations when reset synchronous PWM mode and buffer operation are simultaneously set, refer to section 13.4.8, Buffer Operation.

### 13.4.7 Complementary PWM Mode

Three PWM waveforms for non-overlapped normal and counter phases are output by combining channels 0 and 1.

In complementary PWM mode, the FTIOB0 to FTIOD0 and FTIOA1 to FTIOD1 pins become PWM-output pins automatically. TCNT\_0 and TCNT\_1 perform an increment or decrement operation. Tables 13.6 and 13.7 show the output pins and register settings in complementary PWM mode, respectively.

Figure 13.29 shows the example of complementary PWM mode setting procedure.

**Table 13.6 Output Pins in Complementary PWM Mode**

| Channel | Pin Name | Input/Output | Pin Function                                                           |
|---------|----------|--------------|------------------------------------------------------------------------|
| 0       | FTIOC0   | Output       | Toggle output in synchronous with PWM cycle                            |
| 0       | FTIOB0   | Output       | PWM output 1                                                           |
| 0       | FTIOD0   | Output       | PWM output 1 (counter-phase waveform non-overlapped with PWM output 1) |
| 1       | FTIOA1   | Output       | PWM output 2                                                           |
| 1       | FTIOC1   | Output       | PWM output 2 (counter-phase waveform non-overlapped with PWM output 2) |
| 1       | FTIOB1   | Output       | PWM output 3                                                           |
| 1       | FTIOD1   | Output       | PWM output 3 (counter-phase waveform non-overlapped with PWM output 3) |

**Table 13.7 Register Settings in Complementary PWM Mode**

| Register | Description                                                                                    |
|----------|------------------------------------------------------------------------------------------------|
| TCNT_0   | Initial setting of non-overlapped periods (non-overlapped periods are differences with TCNT_1) |
| TCNT_1   | Initial setting of H'0000                                                                      |
| GRA_0    | Sets (upper limit value – 1) of TCNT_0                                                         |
| GRB_0    | Set a changing point of the PWM waveform output from pins FTIOB0 and FTIOD0.                   |
| GRA_1    | Set a changing point of the PWM waveform output from pins FTIOA1 and FTIOC1.                   |
| GRB_1    | Set a changing point of the PWM waveform output from pins FTIOB1 and FTIOD1.                   |

Note: To re-enter complementary PWM mode, first, enter a mode other than the complementary PWM mode. After that, repeat the setting procedures from step [1].  
 For settings of waveform outputs with a duty cycle of 0% and 100%, see the settings shown in 2. Examples of Complementary PWM Mode Operation and 3. Setting GR Value in Complementary PWM Mode in section 13.4.7.

**Figure 13.29 Example of Complementary PWM Mode Setting Procedure**

1. Canceling Procedure of Complementary PWM Mode: Figure 13.30 shows the complementary PWM mode canceling procedure.

**Figure 13.30 Canceling Procedure of Complementary PWM Mode**

2. Examples of Complementary PWM Mode Operation: Figure 13.31 shows an example of complementary PWM mode operation. In complementary PWM mode, TCNT\_0 and TCNT\_1 perform an increment or decrement operation. When TCNT\_0 and GRA\_0 are compared and their contents match, the counter is decremented, and when TCNT\_1 underflows, the counter is incremented. In GRA\_0, GRA\_1, and GRB\_1, compare match is carried out in the order of TCNT\_0 → TCNT\_1 → TCNT\_1 → TCNT\_0 and PWM waveform is output, during one cycle of a up/down counter. In this mode, the initial setting will be TCNT\_0 > TCNT\_1.

**Figure 13.31 Example of Complementary PWM Mode Operation (1)**

Figure 13.32 (1) and (2) show examples of PWM waveform output with 0% duty and 100% duty in complementary PWM mode (for one phase).

- $TPSC2 = TPSC1 = TPSC0 = 0$

Set GRB\_0 to H'0000 or a value equal to or more than GRA\_0. The waveform with a duty cycle of 0% and 100% can be output. When buffer operation is used together, the duty cycles can easily be changed, including the above settings, during operation. For details on buffer operation, refer to section 13.4.8, Buffer Operation.

- Other than  $TPSC2 = TPSC1 = TPSC0 = 0$

Set GRB\_0 to satisfy the following expression:  $GRA_0 + 1 < GRB_0 < H'FFFF$ . The waveform with a duty cycle of 0% and 100% can be output. For details on 0%- and 100%-duty cycle waveform output, see 3. C., Outputting a waveform with a duty cycle of 0% and 100% in section 13.4.7.

**Figure 13.32 (1) Example of Complementary PWM Mode Operation  
( $TPSC2 = TPSC1 = TPSC0 = 0$ ) (2)**

**Figure 13.32 (2) Example of Complementary PWM Mode Operation  
(TPSC2 = TPSC1 = TPSC0 ≠ 0) (3)**

In complementary PWM mode, when the counter switches from up-counter to down-counter or vice versa, TCNT\_0 and TCNT\_1 overshoots or undershoots, respectively. In this case, the conditions to set the IMFA flag in channel 0 and the UDF flag in channel 1 differ from usual

settings. Also, the transfer conditions in buffer operation differ from usual settings. Such timings are shown in figures 13.33 and 13.34.

**Figure 13.33 Timing of Overshooting**

**Figure 13.34 Timing of Undershooting**

When the counter is incremented or decremented, the IMFA flag of channel 0 is set to 1, and when the register is underflowed, the UDF flag of channel 0 is set to 1. After buffer operation has been designated for BR, BR is transferred to GR when the counter is incremented by compare match A0 or when TCNT\_1 is underflowed. If the  $\phi$  or  $\phi/2$  clock is selected by TPSC2 to TPSC0 bits, the OVF flag is not set to 1 at the timing that the counter value changes from H'FFFF to H'0000. If the  $\phi/4$  or  $\phi/8$  clock is selected by TPSC2 to TPSC0 bits, the OVF flag is set to 1.

3. Setting GR Value in Complementary PWM Mode: To set the general register (GR) or modify GR during operation in complementary PWM mode, refer to the following notes.

A. Initial value

- a. When other than  $TPSC2 = TPSC1 = TPSC0 = 0$ , the  $GRA\_0$  value must be equal to  $H'FFFC$  or less. When  $TPSC2 = TPSC1 = TPSC0 = 0$ , the  $GRA\_0$  value can be set to  $H'FFFF$  or less.
- b.  $H'0000$  to  $T - 1$  ( $T$ : Initial value of  $TCNT0$ ) must not be set for the initial value.
- c.  $GRA\_0 - (T - 1)$  or more must not be set for the initial value.
- d. When using buffer operation, the same values must be set in the buffer registers and corresponding general registers.

B. Modifying the setting value

- a. Writing to GR directly must be performed while the  $TCNT\_1$  and  $TCNT\_0$  values should satisfy the following expression:  $H'0000 \leq TCNT\_1 < \text{previous GR value}$ , and  $\text{previous GR value} < TCNT\_0 \leq GRA\_0$ . Otherwise, a waveform is not output correctly. For details on outputting a waveform with a duty cycle of 0% and 100%, see C., Outputting a waveform with a duty cycle of 0% and 100%.
- b. Do not write the following values to GR directly. When writing the values, a waveform is not output correctly.  
 $H'0000 \leq GR \leq T - 1$  and  $GRA\_0 - (T - 1) \leq GR < GRA\_0$  when  $TPSC2 = TPSC1 = TPSC0 = 0$   
 $H'0000 < GR \leq T - 1$  and  $GRA\_0 - (T - 1) \leq GR < GRA\_0 + 1$  when  $TPSC2 = TPSC1 = TPSC0 = 0$
- c. Do not change settings of  $GRA\_0$  during operation.

C. Outputting a waveform with a duty cycle of 0% and 100%

- a. Buffer operation is not used and  $TPSC2 = TPSC1 = TPSC0 = 0$   
Write  $H'0000$  or a value equal to or more than the  $GRA\_0$  value to GR directly at the timing shown below.
  - To output a 0%-duty cycle waveform, write a value equal to or more than the  $GRA\_0$  value while  $H'0000 \leq TCNT\_1 < \text{previous GR value}$
  - To output a 100%-duty cycle waveform, write  $H'0000$  while  $\text{previous GR value} < TCNT\_0 \leq GRA\_0$

To change duty cycles while a waveform with a duty cycle of 0% or 100% is being output, make sure the following procedure.

- To change duty cycles while a 0%-duty cycle waveform is being output, write to GR while  $H'0000 \leq TCNT\_1 < \text{previous GR value}$
- To change duty cycles while a 100%-duty cycle waveform is being output, write to GR while  $\text{previous GR value} < TCNT\_0 \leq GRA\_0$

Note that changing from a 0%-duty cycle waveform to a 100%-duty cycle waveform and vice versa is not possible.

- b. Buffer operation is used and  $TPSC2 = TPSC1 = TPSC0 = 0$

Write H'0000 or a value equal to or more than the GRA\_0 value to the buffer register.

- To output a 0%-duty cycle waveform, write a value equal to or more than the GRA\_0 value to the buffer register
  - To output a 100%-duty cycle waveform, write H'0000 to the buffer register
- For details on buffer operation, see section 13.4.8, Buffer Operation.

- c. Buffer operation is not used and other than  $TPSC2 = TPSC1 = TPSC0 = 0$

Write a value which satisfies  $GRA_0 + 1 < GR < H'FFFF$  to GR directly at the timing shown below.

- To output a 0%-duty cycle waveform, write the value while  $H'0000 \leq TCNT_1 <$  previous GR value
- To output a 100%-duty cycle waveform, write the value while previous GR value  $< TCNT_0 \leq GRA_0$

To change duty cycles while a waveform with a duty cycle of 0% and 100% is being output, the following procedure must be followed.

- To change duty cycles while a 0%-duty cycle waveform is being output, write to GR while  $H'0000 \leq TCNT_1 <$  previous GR value
- To change duty cycles while a 100%-duty cycle waveform is being output, write to GR while previous GR value  $< TCNT_0 \leq GRA_0$

Note that changing from a 0%-duty cycle waveform to a 100%-duty cycle waveform and vice versa is not possible.

- d. Buffer operation is used and other than  $TPSC2 = TPSC1 = TPSC0 = 0$

Write a value which satisfies  $GRA_0 + 1 < GR < H'FFFF$  to the buffer register. A waveform with a duty cycle of 0% can be output. However, a waveform with a duty cycle of 100% cannot be output using the buffer operation. Also, the buffer operation cannot be used to change duty cycles while a waveform with a duty cycle of 100% is being output. For details on buffer operation, see section 13.4.8, Buffer Operation.

13.4.8 Buffer Operation

Buffer operation differs depending on whether GR has been designated for an input capture register or an output compare register, or in reset synchronous PWM mode or complementary PWM mode.

Table 13.8 shows the register combinations used in buffer operation.

Table 13.8 Register Combinations in Buffer Operation

| General Register | Buffer Register |
|------------------|-----------------|
| GRA              | GRC             |
| GRB              | GRD             |

1. When GR is an output compare register
- When a compare match occurs, the value in the buffer register of the corresponding channel is transferred to the general register.
- This operation is illustrated in figure 13.35.

Figure 13.35 Compare Match Buffer Operation

2. When GR is an input capture register
- When an input capture occurs, the value in TCNT is transferred to the general register and the value previously stored in the general register is transferred to the buffer register.
- This operation is illustrated in figure 13.36.

Figure 13.36 Input Capture Buffer Operation

### 3. Complementary PWM Mode

When the counter switches from counting up to counting down or vice versa, the value of the buffer register is transferred to the general register. Here, the value of the buffer register is transferred to the general register in the following timing:

- A. When TCNT\_0 and GRA\_0 are compared and their contents match
- B. When TCNT\_1 underflows

### 4. Reset Synchronous PWM Mode

The value of the buffer register is transferred from compare match A0 to the general register.

### 5. Example of Buffer Operation Setting Procedure

Figure 13.37 shows an example of the buffer operation setting procedure.

**Figure 13.37 Example of Buffer Operation Setting Procedure**

## 6. Examples of Buffer Operation

Figure 13.38 shows an operation example in which GRA has been designated as an output compare register, and buffer operation has been designated for GRA and GRC.

This is an example of TCNT operating as a periodic counter cleared by compare match B.

Pins FTIOA and FTIOB are set for toggle output by compare match A and B.

As buffer operation has been set, when compare match A occurs, the FTIOA pin performs toggle outputs and the value in buffer register is simultaneously transferred to the general register. This operation is repeated each time that compare match A occurs.

The timing to transfer data is shown in figure 13.39.

**Figure 13.38 Example of Buffer Operation (1)  
(Buffer Operation for Output Compare Register)**

**Figure 13.39 Example of Compare Match Timing for Buffer Operation**

Figure 13.40 shows an operation example in which GRA has been designated as an input capture register, and buffer operation has been designated for GRA and GRC.

Counter clearing by input capture B has been set for TCNT, and falling edges have been selected as the FIOCB pin input capture input edge. And both rising and falling edges have been selected as the FIOCA pin input capture input edge.

As buffer operation has been set, when the TCNT value is stored in GRA upon the occurrence of input capture A, the value previously stored in GRA is simultaneously transferred to GRC. The transfer timing is shown in figure 13.41.

**Figure 13.40 Example of Buffer Operation (2)  
(Buffer Operation for Input Capture Register)**

**Figure 13.41 Input Capture Timing of Buffer Operation**

Figures 13.42 and 13.43 show the operation examples when buffer operation has been designated for GRB\_0 and GRD\_0 in complementary PWM mode. These are examples when a PWM waveform of 0% duty is created by using the buffer operation and performing  $\text{GRD}_0 \geq \text{GRA}_0$ . Data is transferred from GRD\_0 to GRB\_0 according to the settings of CMD\_0 and CMD\_1 when TCNT\_0 and GRA\_0 are compared and their contents match or when TCNT\_1 underflows. However, when  $\text{GRD}_0 \geq \text{GRA}_0$ , data is transferred from GRD\_0 to GRB\_0 when TCNT\_1 underflows regardless of the setting of CMD\_0 and CMD\_1. When  $\text{GRD}_0 = \text{H}'0000$ , data is transferred from GRD\_0 to GRB\_0 when TCNT\_0 and GRA\_0 are compared and their contents match regardless of the settings of CMD\_0 and CMD\_1.

**Figure 13.42 Buffer Operation (3)**  
**(Buffer Operation in Complementary PWM Mode  $CMD1 = CMD0 = 1$ )**

**Figure 13.43 Buffer Operation (4)**  
**(Buffer Operation in Complementary PWM Mode  $CMD1 = CMD0 = 1$ )**

### 13.4.9 Timer Z Output Timing

The outputs of channels 0 and 1 can be disabled or inverted by the settings of TOER and TOCR and the external level.

1. Output Disable/Enable Timing of Timer Z by TOER: Setting the master enable bit in TOER to 1 disables the output of timer Z. By setting the PCR and PDR of the corresponding I/O port beforehand, any value can be output. Figure 13.44 shows the timing to enable or disable the output of timer Z by TOER.

**Figure 13.44 Example of Output Disable Timing of Timer Z by Writing to TOER**

- Output Disable Timing of Timer Z by External Trigger: When P54/ $\overline{\text{WKP4}}$  is set as a  $\overline{\text{WKP4}}$  input pin, and low level is input to  $\overline{\text{WKP4}}$ , the master enable bit in TOER is set to 1 and the output of timer Z will be disabled.

**Figure 13.45 Example of Output Disable Timing of Timer Z by External Trigger**

3. Output Inverse Timing by TFCR: The output level can be inverted by inverting the OLS1 and OLS0 bits in TFCR in reset synchronous PWM mode or complementary PWM mode. Figure 13.46 shows the timing.

**Figure 13.46 Example of Output Inverse Timing of Timer Z by Writing to TFCR**

4. Output Inverse Timing by POCCR: The output level can be inverted by inverting the POLD, POLC, and POLB bits in POCCR in PWM mode. Figure 13.47 shows the timing.

**Figure 13.47 Example of Output Inverse Timing of Timer Z by Writing to POCCR**

## 13.5 Interrupts

There are three kinds of timer Z interrupt sources; input capture/compare match, overflow, and underflow. An interrupt is requested when the corresponding interrupt request flag is set to 1 while the corresponding interrupt enable bit is set to 1.

### 13.5.1 Status Flag Set Timing

1. IMF Flag Set Timing: The IMF flag is set to 1 by the compare match signal that is generated when the GR matches with the TCNT. The compare match signal is generated at the last state of matching (timing to update the counter value when the GR and TCNT match). Therefore, when the TCNT and GR matches, the compare match signal will not be generated until the TCNT input clock is generated. Figure 13.48 shows the timing to set the IMF flag.

**Figure 13.48 IMF Flag Set Timing when Compare Match Occurs**

2. **IMF Flag Set Timing at Input Capture:** When an input capture signal is generated, the IMF flag is set to 1 and the value of TCNT is simultaneously transferred to corresponding GR. Figure 13.49 shows the timing.

**Figure 13.49 IMF Flag Set Timing at Input Capture**

3. **Overflow Flag (OVF) Set Timing:** The overflow flag is set to 1 when the TCNT overflows. Figure 13.50 shows the timing.

**Figure 13.50 OVF Flag Set Timing**

### 13.5.2 Status Flag Clearing Timing

The status flag can be cleared by writing 0 after reading 1 from the CPU. Figure 13.51 shows the timing in this case.

Figure 13.51 Status Flag Clearing Timing

### 13.6 Usage Notes

1. Contention between TCNT Write and Clear Operations: If a counter clear signal is generated in the  $T_2$  state of a TCNT write cycle, TCNT clearing has priority and the TCNT write is not performed. Figure 13.52 shows the timing in this case.

Figure 13.52 Contention between TCNT Write and Clear Operations

2. Contention between TCNT Write and Increment Operations: If incrementation is done in  $T_2$  state of a TCNT write cycle, TCNT writing has priority. Figure 13.53 shows the timing in this case.

**Figure 13.53 Contention between TCNT Write and Increment Operations**

3. Contention between GR Write and Compare Match: If a compare match occurs in the  $T_2$  state of a GR write cycle, GR write has priority and the compare match signal is disabled. Figure 13.54 shows the timing in this case.

**Figure 13.54 Contention between GR Write and Compare Match**

4. Contention between TCNT Write and Overflow/Underflow: If overflow/underflow occurs in the  $T_2$  state of a TCNT write cycle, TCNT write has priority without an increment operation. At this time, the OVF flag is set to 1. Figure 13.55 shows the timing in this case.

**Figure 13.55 Contention between TCNT Write and Overflow**

5. **Contention between GR Read and Input Capture:** If an input capture signal is generated in the  $T_1$  state of a GR read cycle, the data that is read will be transferred before input capture transfer. Figure 13.56 shows the timing in this case.

**Figure 13.56 Contention between GR Read and Input Capture**

6. Contention between Count Clearing and Increment Operations by Input Capture: If an input capture and increment signals are simultaneously generated, count clearing by the input capture operation has priority without an increment operation. The TCNT contents before clearing counter are transferred to GR. Figure 13.57 shows the timing in this case.

**Figure 13.57 Contention between Count Clearing and Increment Operations by Input Capture**

7. **Contention between GR Write and Input Capture:** If an input capture signal is generated in the  $T_2$  state of a GR write cycle, the input capture operation has priority and the write to GR is not performed. Figure 13.58 shows the timing in this case.

**Figure 13.58 Contention between GR Write and Input Capture**

8. **Notes on Setting Reset Synchronous PWM Mode/Complementary PWM Mode:** When bits CMD1 and CMD0 in TFCR are set, note the following:
- A. Write bits CMD1 and CMD0 while TCNT\_1 and TCNT\_0 are halted.
  - B. Changing the settings of reset synchronous PWM mode to complementary PWM mode or vice versa is disabled. Set reset synchronous PWM mode or complementary PWM mode after the normal operation (bits CMD1 and CMD0 are cleared to 0) has been set.
9. **Note on Clearing TSR Flag:** When a specific flag in TSR is cleared, a combination of the BCLR or MOV instructions is used to read 1 from the flag and then write 0 to the flag. However, if another bit is set during this processing, the bit may also be cleared simultaneously. To avoid this, the following processing that does not use the BCLR instruction must be executed. Note that this note is only applied to the F-ZTAT version. This problem has already been solved in the mask ROM version.

Example: When clearing bit 4 (OVF) in TSR

```
MOV.B @TSR,R0L
```

```
MOV.B #B'11101111, R0L
```

← Only the bit to be cleared is 0 and  
the other bits are all set to 1.

```
MOV.B R0L,@TSR
```

# 10. Note on Writing to the TOA0 to TOD0 Bits and the TOA1 to TOD1 Bits in TOCR:

The TOA0 to TOD0 bits and the TOA1 to TOD1 bits in TOCR decide the value of the FTIO pin, which is output until the first compare match occurs. Once a compare match occurs and this compare match changes the values of FTIOA0 to FTIOD0 and FTIOA1 to FTIOD1 output, the values of the FTIOA0 to FTIOD0 and FTIOA1 to FTIOD1 pin output and the values read from the TOA0 to TOD0 and TOA1 to TOD1 bits may differ. Moreover, when the writing to TOCR and the generation of the compare match A0 to D0 and A1 to D1 occur at the same timing, the writing to TOCR has the priority. Thus, output change due to the compare match is not reflected to the FTIOA0 to FTIOD0 and FTIOA1 to FTIOD1 pins. Therefore, when bit manipulation instruction is used to write to TOCR, the values of the FTIOA0 to FTIOD0 and FTIOA1 to FTIOD1 pin output may result in an unexpected result. When TOCR is to be written to while compare match is operating, stop the counter once before accessing to TOCR, read the port 6 state to reflect the values of FTIOA0 to FTIOD0 and FTIOA1 to FTIOD1 output, to TOA0 to TOD0 and TOA1 to TOD1, and then restart the counter. Figure 13.59 shows an example when the compare match and the bit manipulation instruction to TOCR occur at the same timing.

TOCR has been set to H'06. Compare match B0 and compare match C0 are used. The FTIOB0 pin is in the 1 output state, and is set to the toggle output or the 0 output by compare match B0.

When BCLR#2, @TOCR is executed to clear the TOC0 bit (the FTIOC0 signal is low) and compare match B0 occurs at the same timing as shown below, the H'02 writing to TOCR has priority and compare match B0 does not drive the FTIOB0 signal low; the FTIOB0 signal remains high.

| Bit       | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|-----------|------|------|------|------|------|------|------|------|
| TOCR      | TOD1 | TOC1 | TOB1 | TOA1 | TOD0 | TOC0 | TOB0 | TOA0 |
| Set value | 0    | 0    | 0    | 0    | 0    | 1    | 1    | 0    |

BCLR#2, @TOCR

- (1) TOCR read operation: Read H'06
- (2) Modify operation: Modify H'06 to H'02
- (3) Write operation to TOCR: Write H'02

**Figure 13.59 When Compare Match and Bit Manipulation Instruction to TOCR Occur at the Same Timing**

## Section 14 Watchdog Timer

The watchdog timer is an 8-bit timer that can generate an internal reset signal for this LSI if a system crash prevents the CPU from writing to the timer counter, thus allowing it to overflow.

The block diagram of the watchdog timer is shown in figure 14.1.

**Figure 14.1 Block Diagram of Watchdog Timer**

### 14.1 Features

- Selectable from nine counter input clocks.  
Eight clock sources ( $\phi/64$ ,  $\phi/128$ ,  $\phi/256$ ,  $\phi/512$ ,  $\phi/1024$ ,  $\phi/2048$ ,  $\phi/4096$ , and  $\phi/8192$ ) or the internal oscillator can be selected as the timer-counter clock. When the internal oscillator is selected, it can operate as the watchdog timer in any operating mode.
- Reset signal generated on counter overflow  
An overflow period of 1 to 256 times the selected clock can be set.

### 14.2 Register Descriptions

The watchdog timer has the following registers.

- Timer control/status register WD (TCSRWD)
- Timer counter WD (TCWD)
- Timer mode register WD (TMWD)

### 14.2.1 Timer Control/Status Register WD (TCSRWD)

TCSRWD performs the TCSRWD and TCWD write control. TCSRWD also controls the watchdog timer operation and indicates the operating state. TCSRWD must be rewritten by using the MOV instruction. The bit manipulation instruction cannot be used to change the setting value.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 14.2.2 Timer Counter WD (TCWD)

TCWD is an 8-bit readable/writable up-counter. When TCWD overflows from H'FF to H'00, the internal reset signal is generated and the WRST bit in TCSRWD is set to 1. TCWD is initialized to H'00.

### 14.2.3 Timer Mode Register WD (TMWD)

TMWD selects the input clock.

Legend X: Don't care.

## 14.3 Operation

The watchdog timer is provided with an 8-bit counter. If 1 is written to WDON while writing 0 to B2WI when the TCSRWE bit in TCSRWD is set to 1, TCWD begins counting up. (To operate the watchdog timer, two write accesses to TCSRWD are required.) When a clock pulse is input after the TCWD count value has reached H'FF, the watchdog timer overflows and an internal reset signal is generated. The internal reset signal is output for a period of  $256 \phi_{osc}$  clock cycles. TCWD is a writable counter, and when a value is set in TCWD, the count-up starts from that value. An overflow period in the range of 1 to 256 input clock cycles can therefore be set, according to the TCWD set value.

Figure 14.2 shows an example of watchdog timer operation.

**Figure 14.2 Watchdog Timer Operation Example**

## Section 15 14-Bit PWM

The 14-bit PWM is a pulse division type PWM that can be used for electronic tuner control, etc. Figure 15.1 shows a block diagram of the 14-bit PWM.

### 15.1 Features

- Choice of two conversion periods  
A conversion period of  $32768/\phi$  with a minimum modulation width of  $2/\phi$ , or a conversion period of  $16384/\phi$  with a minimum modulation width of  $1/\phi$ , can be selected.
- Pulse division method for less ripple

**Figure 15.1 Block Diagram of 14-Bit PWM**

## 15.2 Input/Output Pin

Table 15.1 shows the 14-bit PWM pin configuration.

**Table 15.1 Pin Configuration**

| Name                          | Abbreviation | I/O    | Function                          |
|-------------------------------|--------------|--------|-----------------------------------|
| 14-bit PWM square-wave output | PWM          | Output | 14-bit PWM square-wave output pin |

## 15.3 Register Descriptions

The 14-bit PWM has the following registers.

- PWM control register (PWCR)
- PWM data register U (PWDRU)
- PWM data register L (PWDRL)

### 15.3.1 PWM Control Register (PWCR)

PWCR selects the conversion period.

Legend  $t\phi$ : Period of PWM clock input

### 15.3.2 PWM Data Registers U and L (PWDRU, PWDRL)

PWDRU and PWDRL indicate high level width in one PWM waveform cycle. PWDRU and PWDRL are 14-bit write-only registers, with the upper 6 bits assigned to PWDRU and the lower 8 bits to PWDRL. When read, all bits are always read as 1.

Both PWDRU and PWDRL are accessible only in bytes. Note that the operation is not guaranteed if word access is performed. When 14-bit data is written in PWDRU and PWDRL, the contents are latched in the PWM waveform generator and the PWM waveform generation data is updated. When writing the 14-bit data, the order is as follows: PWDRL to PWDRU.

PWDRU and PWDRL are initialized to H'C000.

## 15.4 Operation

When using the 14-bit PWM, set the registers in this sequence:

1. Set the PWM bit in the port mode register 1 (PMR1) to set the P11/PWM pin to function as a PWM output pin.
2. Set the PWCR0 bit in PWCR to select a conversion period of either.
3. Set the output waveform data in PWDRU and PWDRL. Be sure to write byte data first to PWDRL and then to PWDRU. When the data is written in PWDRU, the contents of these registers are latched in the PWM waveform generator, and the PWM waveform generation data is updated in synchronization with internal signals.

One conversion period consists of 64 pulses, as shown in figure 15.2. The total high-level width during this period ( $T_H$ ) corresponds to the data in PWDRU and PWDRL. This relation can be expressed as follows:

$$T_H = (\text{data value in PWDRU and PWDRL} + 64) \times t\phi/2$$

where  $t\phi$  is the period of PWM clock input:  $2/\phi$  (bit PWCR0 = 0) or  $4/\phi$  (bit PWCR0 = 1).

If the data value in PWDRU and PWDRL is from H'FFC0 to H'FFFF, the PWM output stays high. When the data value is H'C000,  $T_H$  is calculated as follows:

$$T_H = 64 \times t\phi/2 = 32 t\phi$$

**Figure 15.2 Waveform Output by 14-Bit PWM**

# Section 16 Serial Communication Interface 3 (SCI3)

This LSI includes a serial communication interface 3 (SCI3), which has independent two channels. The SCI3 can handle both asynchronous and clocked synchronous serial communication. In asynchronous mode, serial data communication can be carried out using standard asynchronous communication chips such as a Universal Asynchronous Receiver/Transmitter (UART) or an Asynchronous Communication Interface Adapter (ACIA). A function is also provided for serial communication between processors (multiprocessor communication function).

Table 16.1 shows the SCI3 channel configuration and figure 16.1 shows a block diagram of the SCI3. Since pin functions are identical for each of the two channels (SCI3 and SCI3\_2), separate explanations are not given in this section.

## 16.1 Features

- Choice of asynchronous or clocked synchronous serial communication mode
- Full-duplex communication capability

The transmitter and receiver are mutually independent, enabling transmission and reception to be executed simultaneously.

Double-buffering is used in both the transmitter and the receiver, enabling continuous transmission and continuous reception of serial data.

- On-chip baud rate generator allows any bit rate to be selected
- External clock or on-chip baud rate generator can be selected as a transfer clock source.
- Six interrupt sources

Transmit-end, transmit-data-empty, receive-data-full, overrun error, framing error, and parity error.

### Asynchronous mode

- Data length: 7 or 8 bits
- Stop bit length: 1 or 2 bits
- Parity: Even, odd, or none
- Receive error detection: Parity, overrun, and framing errors
- Break detection: Break can be detected by reading the RxD pin level directly in the case of a framing error

### Clocked synchronous mode

- Data length: 8 bits
- Receive error detection: Overrun errors

**Table 16.1 Channel Configuration**

| Channel   | Abbreviation | Pin                      | Register | Register Address |

## 16.2 Input/Output Pins

Table 16.2 shows the SCI3 pin configuration.

**Table 16.2 Pin Configuration**

| Pin Name                  | Abbreviation | I/O    | Function                  |
|---------------------------|--------------|--------|---------------------------|
| SCI3 clock                | SCK3         | I/O    | SCI3 clock input/output   |
| SCI3 receive data input   | RXD          | Input  | SCI3 receive data input   |
| SCI3 transmit data output | TXD          | Output | SCI3 transmit data output |

## 16.3 Register Descriptions

The SCI3 has the following registers for each channel.

- Receive Shift Register (RSR)
- Receive Data Register (RDR)
- Transmit Shift Register (TSR)
- Transmit Data Register (TDR)
- Serial Mode Register (SMR)
- Serial Control Register 3 (SCR3)
- Serial Status Register (SSR)
- Bit Rate Register (BRR)

### **16.3.1 Receive Shift Register (RSR)**

RSR is a shift register that is used to receive serial data input from the RxD pin and convert it into parallel data. When one frame of data has been received, it is transferred to RDR automatically. RSR cannot be directly accessed by the CPU.

### **16.3.2 Receive Data Register (RDR)**

RDR is an 8-bit register that stores received data. When the SCI3 has received one frame of serial data, it transfers the received serial data from RSR to RDR, where it is stored. After this, RSR is receive-enabled. As RSR and RDR function as a double buffer in this way, continuous receive operations are possible. After confirming that the RDRF bit in SSR is set to 1, read RDR only once. RDR cannot be written to by the CPU. RDR is initialized to H'00.

### **16.3.3 Transmit Shift Register TSR (SCI3)**

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI3 first transfers transmit data from TDR to TSR automatically, then sends the data that starts from the LSB to the TXD pin. TSR cannot be directly accessed by the CPU.

### **16.3.4 Transmit Data Register (TDR)**

TDR is an 8-bit register that stores data for transmission. When the SCI3 detects that TSR is empty, it transfers the transmit data written in TDR to TSR and starts transmission. The double-buffered structure of TDR and TSR enables continuous serial transmission. If the next transmit data has already been written to TDR during transmission of one-frame data, the SCI3 transfers the written data to TSR to continue transmission. To achieve reliable serial transmission, write transmit data to TDR only once after confirming that the TDRE bit in SSR is set to 1. TDR is initialized to H'FF.

### 16.3.5 Serial Mode Register (SMR)

SMR is used to set the SCI3's serial transfer format and select the baud rate generator clock source.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                  |

### 16.3.6 Serial Control Register 3 (SCR3)

SCR3 is a register that enables or disables SCI3 transfer operations and interrupt requests, and is also used to select the transfer clock source. For details on interrupt requests, refer to section 16.7, Interrupts.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 16.3.7 Serial Status Register (SSR)

SSR is a register containing status flags of the SCI3 and multiprocessor bits for transfer. 1 cannot be written to flags TDRE, RDRF, OER, PER, and FER; they can only be cleared.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 16.3.8 Bit Rate Register (BRR)

BRR is an 8-bit register that adjusts the bit rate. The initial value of BRR is H'FF. Table 16.3 shows the relationship between the N setting in BRR and the n setting in bits CKS1 and CKS0 of SMR in asynchronous mode. Table 16.4 shows the maximum bit rate for each frequency in asynchronous mode. The values shown in both tables 16.3 and 16.4 are values in active (high-speed) mode. Table 16.5 shows the relationship between the N setting in BRR and the n setting in bits CKS1 and CKS0 of SMR in clocked synchronous mode. The values shown in table 16.5 are values in active (high-speed) mode. The N setting in BRR and error for other operating frequencies and bit rates can be obtained by the following formulas:

#### [Asynchronous Mode]

$$N = \frac{\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

$$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

#### [Clocked Synchronous Mode]

$$N = \frac{\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

Legend B: Bit rate (bit/s)

N: BRR setting for baud rate generator ( $0 \leq N \leq 255$ )

$\phi$ : Operating frequency (MHz)

n: CSK1 and CSK0 settings in SMR ( $0 \leq n \leq 3$ )

**Table 16.3 Examples of BRR Settings for Various Bit Rates (Asynchronous Mode) (1)**

| Bit Rate<br>(bits/s) | Operating Frequency $\phi$ (MHz) |     |           |          |     |           |        |     |           |   |     |           |

## 16.4 Operation in Asynchronous Mode

Figure 16.2 shows the general format for asynchronous serial communication. One character (or frame) consists of a start bit (low level), followed by data (in LSB-first order), a parity bit (high or low level), and finally stop bits (high level). Inside the SCI3, the transmitter and receiver are independent units, enabling full-duplex. Both the transmitter and the receiver also have a double-buffered structure, so data can be read or written during transmission or reception, enabling continuous data transfer.

**Figure 16.2 Data Format in Asynchronous Communication**

### 16.4.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input at the SCK3 pin can be selected as the SCI3's serial clock, according to the setting of the COM bit in SMR and the CKE0 and CKE1 bits in SCR3. When an external clock is input at the SCK3 pin, the clock frequency should be 16 times the bit rate used.

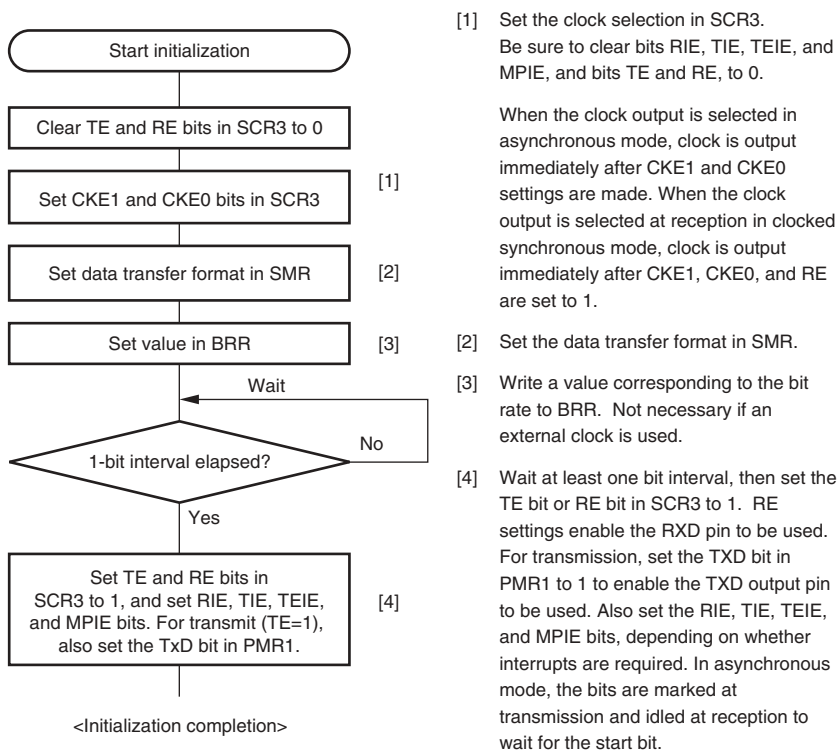

When the SCI3 is operated on an internal clock, the clock can be output from the SCK3 pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in figure 16.3.

**Figure 16.3 Relationship between Output Clock and Transfer Data Phase (Asynchronous Mode)(Example with 8-Bit Data, Parity, Two Stop Bits)**

## 16.4.2 SCI3 Initialization

Before transmitting and receiving data, you should first clear the TE and RE bits in SCR3 to 0, then initialize the SCI3 as described below. When the operating mode, or transfer format, is changed for example, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, the TDRE flag is set to 1. Note that clearing the RE bit to 0 does not initialize the contents of the RDRF, PER, FER, and OER flags, or the contents of RDR. When the external clock is used in asynchronous mode, the clock must be supplied even during initialization.

**Figure 16.4 Sample SCI3 Initialization Flowchart**

### 16.4.3 Data Transmission

Figure 16.5 shows an example of operation for transmission in asynchronous mode. In transmission, the SCI3 operates as described below.

1. The SCI3 monitors the TDRE flag in SSR. If the flag is cleared to 0, the SCI3 recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
2. After transferring data from TDR to TSR, the SCI3 sets the TDRE flag to 1 and starts transmission. If the TIE bit is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is possible because the TXI interrupt routine writes next transmit data to TDR before transmission of the current transmit data has been completed.
3. The SCI3 checks the TDRE flag at the timing for sending the stop bit.
4. If the TDRE flag is 0, the data is transferred from TDR to TSR, the stop bit is sent, and then serial transmission of the next frame is started.
5. If the TDRE flag is 1, the TEND flag in SSR is set to 1, the stop bit is sent, and then the “mark state” is entered, in which 1 is output. If the TEIE bit in SCR3 is set to 1 at this time, a TEI interrupt request is generated.
6. Figure 16.6 shows a sample flowchart for transmission in asynchronous mode.

**Figure 16.5 Example of SCI3 Transmission in Asynchronous Mode  
(8-Bit Data, Parity, One Stop Bit)**

- [1] Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR. When data is written to TDR, the TDRE flag is automatically cleared to 0.
- [2] To continue serial transmission, read 1 from the TDRE flag to confirm that writing is possible, then write data to TDR. When data is written to TDR, the TDRE flag is automatically cleared to 0.
- [3] To output a break in serial transmission, after setting PCR to 1 and PDR to 0, clear TxD in PMR1 to 0, then clear the TE bit in SCR3 to 0.

**Figure 16.6 Sample Serial Transmission Data Flowchart (Asynchronous Mode)**

## 16.4.4 Serial Data Reception

Figure 16.7 shows an example of operation for reception in asynchronous mode. In serial reception, the SCI3 operates as described below.

1. The SCI3 monitors the communication line. If a start bit is detected, the SCI3 performs internal synchronization, receives receive data in RSR, and checks the parity bit and stop bit.
2. If an overrun error occurs (when reception of the next data is completed while the RDRF flag is still set to 1), the OER bit in SSR is set to 1. If the RIE bit in SCR3 is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR.
3. If a parity error is detected, the PER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR3 is set to 1 at this time, an ERI interrupt request is generated.
4. If a framing error is detected (when the stop bit is 0), the FER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR3 is set to 1 at this time, an ERI interrupt request is generated.
5. If reception is completed successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR3 is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is possible because the RXI interrupt routine reads the receive data transferred to RDR before reception of the next receive data has been completed.

**Figure 16.7 Example of SCI3 Reception in Asynchronous Mode  
(8-Bit Data, Parity, One Stop Bit)**

Table 16.6 shows the states of the SSR status flags and receive data handling when a receive error is detected. If a receive error is detected, the RDRF flag retains its state before receiving data. Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the OER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 16.8 shows a sample flow chart for serial data reception.

**Table 16.6 SSR Status Flags and Receive Data Handling**

| SSR Status Flag |     |     |     | Receive Data       | Receive Error Type                           |
|-----------------|-----|-----|-----|--------------------|----------------------------------------------|
| RDRF*           | OER | FER | PER |                    |                                              |
| 1               | 1   | 0   | 0   | Lost               | Overrun error                                |
| 0               | 0   | 1   | 0   | Transferred to RDR | Framing error                                |
| 0               | 0   | 0   | 1   | Transferred to RDR | Parity error                                 |
| 1               | 1   | 1   | 0   | Lost               | Overrun error + framing error                |
| 1               | 1   | 0   | 1   | Lost               | Overrun error + parity error                 |
| 0               | 0   | 1   | 1   | Transferred to RDR | Framing error + parity error                 |
| 1               | 1   | 1   | 1   | Lost               | Overrun error + framing error + parity error |

Note: \* The RDRF flag retains the state it had before data reception.

**Figure 16.8 Sample Serial Reception Data Flowchart (Asynchronous Mode)(1)**

**Figure 16.8 Sample Serial Reception Data Flowchart (Asynchronous Mode)(2)**

## 16.5 Operation in Clocked Synchronous Mode

Figure 16.9 shows the general format for clocked synchronous communication. In clocked synchronous mode, data is transmitted or received synchronous with clock pulses. A single character in the transmit data consists of the 8-bit data starting from the LSB. In clocked synchronous serial communication, data on the transmission line is output from one falling edge of the synchronization clock to the next. In clocked synchronous mode, the SCI3 receives data in synchronous with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the MSB state. In clocked synchronous mode, no parity or multiprocessor bit is added. Inside the SCI3, the transmitter and receiver are independent units, enabling full-duplex communication through the use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so data can be read or written during transmission or reception, enabling continuous data transfer.

**Figure 16.9 Data Format in Clocked Synchronous Communication**

### 16.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCK3 pin can be selected, according to the setting of the COM bit in SMR and CKE0 and CKE1 bits in SCR3. When the SCI3 is operated on an internal clock, the synchronization clock is output from the SCK3 pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is fixed high.

### 16.5.2 SCI3 Initialization

Before transmitting and receiving data, the SCI3 should be initialized as described in a sample flowchart in figure 16.4.

### 16.5.3 Serial Data Transmission

Figure 16.10 shows an example of SCI3 operation for transmission in clocked synchronous mode. In serial transmission, the SCI3 operates as described below.

1. The SCI3 monitors the TDRE flag in SSR, and if the flag is 0, the SCI3 recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
2. The SCI3 sets the TDRE flag to 1 and starts transmission. If the TIE bit in SCR3 is set to 1 at this time, a transmit data empty interrupt (TXI) is generated.
3. 8-bit data is sent from the TxD pin synchronized with the output clock when output clock mode has been specified, and synchronized with the input clock when use of an external clock has been specified. Serial data is transmitted sequentially from the LSB (bit 0), from the TxD pin.
4. The SCI3 checks the TDRE flag at the timing for sending the MSB (bit 7).
5. If the TDRE flag is cleared to 0, data is transferred from TDR to TSR, and serial transmission of the next frame is started.
6. If the TDRE flag is set to 1, the TEND flag in SSR is set to 1, and the TDRE flag maintains the output state of the last bit. If the TEIE bit in SCR3 is set to 1 at this time, a TEI interrupt request is generated.
7. The SCK3 pin is fixed high at the end of transmission.

Figure 16.11 shows a sample flow chart for serial data transmission. Even if the TDRE flag is cleared to 0, transmission will not start while a receive error flag (OER, FER, or PER) is set to 1. Make sure that the receive error flags are cleared to 0 before starting transmission.

**Figure 16.10 Example of SCI3 Transmission in Clocked Synchronous Mode**

- [1] Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR. When data is written to TDR, the TDRE flag is automatically cleared to 0 and clocks are output to start the data transmission.
- [2] To continue serial transmission, be sure to read 1 from the TDRE flag to confirm that writing is possible, then write data to TDR. When data is written to TDR, the TDRE flag is automatically cleared to 0.

**Figure 16.11 Sample Serial Transmission Flowchart (Clocked Synchronous Mode)**

## 16.5.4 Serial Data Reception (Clocked Synchronous Mode)

Figure 16.12 shows an example of SCI3 operation for reception in clocked synchronous mode. In serial reception, the SCI3 operates as described below.

1. The SCI3 performs internal initialization synchronous with a synchronization clock input or output, starts receiving data.
2. The SCI3 stores the receive data in RSR.
3. If an overrun error occurs (when reception of the next data is completed while the RDRF flag in SSR is still set to 1), the OER bit in SSR is set to 1. If the RIE bit in SCR3 is set to 1 at this time, an ERI interrupt request is generated, receive data is not transferred to RDR, and the RDRF flag remains to be set to 1.
4. If reception is completed successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR3 is set to 1 at this time, an RXI interrupt request is generated.

**Figure 16.12 Example of SCI3 Reception in Clocked Synchronous Mode**

Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the OER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 16.13 shows a sample flow chart for serial data reception.

- [1] Read the OER flag in SSR to determine if there is an error. If an overrun error has occurred, execute overrun error processing.
- [2] Read SSR and check that the RDRF flag is set to 1, then read the receive data in RDR. When data is read from RDR, the RDRF flag is automatically cleared to 0.
- [3] To continue serial reception, before the MSB (bit 7) of the current frame is received, reading the RDRF flag and reading RDR should be finished. When data is read from RDR, the RDRF flag is automatically cleared to 0.
- [4] If an overrun error occurs, read the OER flag in SSR, and after performing the appropriate error processing, clear the OER flag to 0. Reception cannot be resumed if the OER flag is set to 1.

**Figure 16.13 Sample Serial Reception Flowchart (Clocked Synchronous Mode)**

### 16.5.5 Simultaneous Serial Data Transmission and Reception

Figure 16.14 shows a sample flowchart for simultaneous serial transmit and receive operations. The following procedure should be used for simultaneous serial data transmit and receive operations. To switch from transmit mode to simultaneous transmit and receive mode, after checking that the SCI3 has finished transmission and the TDRE and TEND flags are set to 1, clear TE to 0. Then simultaneously set TE and RE to 1 with a single instruction. To switch from receive mode to simultaneous transmit and receive mode, after checking that the SCI3 has finished reception, clear RE to 0. Then after checking that the RDRF and receive error flags (OER, FER, and PER) are cleared to 0, simultaneously set TE and RE to 1 with a single instruction.

- [1] Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR.  
When data is written to TDR, the TDRE flag is automatically cleared to 0.
- [2] Read SSR and check that the RDRF flag is set to 1, then read the receive data in RDR.  
When data is read from RDR, the RDRF flag is automatically cleared to 0.
- [3] To continue serial transmission/reception, before the MSB (bit 7) of the current frame is received, finish reading the RDRF flag, reading RDR. Also, before the MSB (bit 7) of the current frame is transmitted, read 1 from the TDRE flag to confirm that writing is possible. Then write data to TDR.  
When data is written to TDR, the TDRE flag is automatically cleared to 0. When data is read from RDR, the RDRF flag is automatically cleared to 0.
- [4] If an overrun error occurs, read the OER flag in SSR, and after performing the appropriate error processing, clear the OER flag to 0. Transmission/reception cannot be resumed if the OER flag is set to 1. For overrun error processing, see figure 16.13.

**Figure 16.14 Sample Flowchart of Simultaneous Serial Transmit and Receive Operations (Clocked Synchronous Mode)**

## 16.6 Multiprocessor Communication Function

Use of the multiprocessor communication function enables data transfer between a number of processors sharing communication lines by asynchronous serial communication using the multiprocessor format, in which a multiprocessor bit is added to the transfer data. When multiprocessor communication is performed, each receiving station is addressed by a unique ID code. The serial communication cycle consists of two component cycles; an ID transmission cycle that specifies the receiving station, and a data transmission cycle. The multiprocessor bit is used to differentiate between the ID transmission cycle and the data transmission cycle. If the multiprocessor bit is 1, the cycle is an ID transmission cycle; if the multiprocessor bit is 0, the cycle is a data transmission cycle. Figure 16.15 shows an example of inter-processor communication using the multiprocessor format. The transmitting station first sends the ID code of the receiving station with which it wants to perform serial communication as data with a 1 multiprocessor bit added. It then sends transmit data as data with a 0 multiprocessor bit added. When data with a 1 multiprocessor bit is received, the receiving station compares that data with its own ID. The station whose ID matches then receives the data sent next. Stations whose IDs do not match continue to skip data until data with a 1 multiprocessor bit is again received.

The SCI3 uses the MPIE bit in SCR3 to implement this function. When the MPIE bit is set to 1, transfer of receive data from RSR to RDR, error flag detection, and setting the SSR status flags, RDRF, FER, and OER, to 1, are inhibited until data with a 1 multiprocessor bit is received. On reception of a receive character with a 1 multiprocessor bit, the MPBR bit in SSR is set to 1 and the MPIE bit is automatically cleared, thus normal reception is resumed. If the RIE bit in SCR3 is set to 1 at this time, an RXI interrupt is generated.

When the multiprocessor format is selected, the parity bit setting is rendered invalid. All other bit settings are the same as those in normal asynchronous mode. The clock used for multiprocessor communication is the same as that in normal asynchronous mode.

**Figure 16.15 Example of Inter-Processor Communication Using Multiprocessor Format  
(Transmission of Data H'AA to Receiving Station A)**

## 16.6.1 Multiprocessor Serial Data Transmission

Figure 16.16 shows a sample flowchart for multiprocessor serial data transmission. For an ID transmission cycle, set the MPBT bit in SSR to 1 before transmission. For a data transmission cycle, clear the MPBT bit in SSR to 0 before transmission. All other SCI3 operations are the same as those in asynchronous mode.

**Figure 16.16 Sample Multiprocessor Serial Transmission Flowchart**

## 16.6.2 Multiprocessor Serial Data Reception

Figure 16.17 shows a sample flowchart for multiprocessor serial data reception. If the MPIE bit in SCR3 is set to 1, data is skipped until data with a 1 multiprocessor bit is sent. On receiving data with a 1 multiprocessor bit, the receive data is transferred to RDR. An RXI interrupt request is generated at this time. All other SCI3 operations are the same as those in asynchronous mode. Figure 16.18 shows an example of SCI3 operation for multiprocessor format reception.

**Figure 16.17 Sample Multiprocessor Serial Reception Flowchart (1)**

**Figure 16.17 Sample Multiprocessor Serial Reception Flowchart (2)**

(a) When data does not match this receiver's ID

(b) When data matches this receiver's ID

**Figure 16.18 Example of SCI3 Reception Using Multiprocessor Format  
(Example with 8-Bit Data, Multiprocessor Bit, One Stop Bit)**

## 16.7 Interrupts

SCI3 creates the following six interrupt requests: transmission end, transmit data empty, receive data full, and receive errors (overrun error, framing error, and parity error). Table 16.7 shows the interrupt sources.

**Table 16.7 SCI3 Interrupt Requests**

| Interrupt Requests  | Abbreviation | Interrupt Sources                |
|---------------------|--------------|----------------------------------|
| Receive Data Full   | RXI          | Setting RDRF in SSR              |
| Transmit Data Empty | TXI          | Setting TDRE in SSR              |
| Transmission End    | TEI          | Setting TEND in SSR              |
| Receive Error       | ERI          | Setting OER, FER, and PER in SSR |

The initial value of the TDRE flag in SSR is 1. Thus, when the TIE bit in SCR3 is set to 1 before transferring the transmit data to TDR, a TXI interrupt request is generated even if the transmit data is not ready. The initial value of the TEND flag in SSR is 1. Thus, when the TEIE bit in SCR3 is set to 1 before transferring the transmit data to TDR, a TEI interrupt request is generated even if the transmit data has not been sent. It is possible to make use of the most of these interrupt requests efficiently by transferring the transmit data to TDR in the interrupt routine. To prevent the generation of these interrupt requests (TXI and TEI), set the enable bits (TIE and TEIE) that correspond to these interrupt requests to 1, after transferring the transmit data to TDR.

## 16.8 Usage Notes

### 16.8.1 Break Detection and Processing

When framing error detection is performed, a break can be detected by reading the RxD pin value directly. In a break, the input from the RxD pin becomes all 0s, setting the FER flag, and possibly the PER flag. Note that as the SCI3 continues the receive operation after receiving a break, even if the FER flag is cleared to 0, it will be set to 1 again.

### 16.8.2 Mark State and Break Sending

When TE is 0, the TxD pin is used as an I/O port whose direction (input or output) and level are determined by PCR and PDR. This can be used to set the TxD pin to mark state (high level) or send a break during serial data transmission. To maintain the communication line at mark state until TE is set to 1, set both PCR and PDR to 1. As TE is cleared to 0 at this point, the TxD pin becomes an I/O port, and 1 is output from the TxD pin. To send a break during serial transmission, first set PCR to 1 and clear PDR to 0, and then clear TE to 0. When TE is cleared to 0, the transmitter is initialized regardless of the current transmission state, the TxD pin becomes an I/O port, and 0 is output from the TxD pin.

### 16.8.3 Receive Error Flags and Transmit Operations (Clocked Synchronous Mode Only)

Transmission cannot be started when a receive error flag (OER, PER, or FER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note also that receive error flags cannot be cleared to 0 even if the RE bit is cleared to 0.

## 16.8.4 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI3 operates on a basic clock with a frequency of 16 times the transfer rate. In reception, the SCI3 samples the falling edge of the start bit using the basic clock, and performs internal synchronization. Receive data is latched internally at the rising edge of the 8th pulse of the basic clock as shown in figure 16.19. Thus, the reception margin in asynchronous mode is given by formula (1) below.

$$M = \left\{ \left( 0.5 - \frac{1}{2N} \right) - \frac{D - 0.5}{N} - (L - 0.5) F \right\} \times 100(\%)$$

... Formula (1)

Legend N : Ratio of bit rate to clock (N = 16)

D : Clock duty (D = 0.5 to 1.0)

L : Frame length (L = 9 to 12)

F : Absolute value of clock rate deviation

Assuming values of F (absolute value of clock rate deviation) = 0 and D (clock duty) = 0.5 in formula (1), the reception margin can be given by the formula.

$$M = \{ 0.5 - 1/(2 \times 16) \} \times 100 [\%] = 46.875\%$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed for in system design.

**Figure 16.19 Receive Data Sampling Timing in Asynchronous Mode**

# Section 17 I<sup>2</sup>C Bus Interface 2 (IIC2)

The I<sup>2</sup>C bus interface 2 conforms to and provides a subset of the Philips I<sup>2</sup>C bus (inter-IC bus) interface functions. The register configuration that controls the I<sup>2</sup>C bus differs partly from the Philips configuration, however.

Figure 17.1 shows a block diagram of the I<sup>2</sup>C bus interface 2.

Figure 17.2 shows an example of I/O pin connections to external circuits.

## 17.1 Features

- Selection of I<sup>2</sup>C format or clocked synchronous serial format
- Continuous transmission/reception  
Since the shift register, transmit data register, and receive data register are independent from each other, the continuous transmission/reception can be performed.

### I<sup>2</sup>C bus format

- Start and stop conditions generated automatically in master mode
- Selection of acknowledge output levels when receiving
- Automatic loading of acknowledge bit when transmitting
- Bit synchronization/wait function

In master mode, the state of SCL is monitored per bit, and the timing is synchronized automatically.

If transmission/reception is not yet possible, set the SCL to low until preparations are completed.

- Six interrupt sources  
Transmit data empty (including slave-address match), transmit end, receive data full (including slave-address match), arbitration lost, NACK detection, and stop condition detection
- Direct bus drive  
Two pins, SCL and SDA pins, function as NMOS open-drain outputs when the bus drive function is selected.

### Clocked synchronous format

- Four interrupt sources  
Transmit-data-empty, transmit-end, receive-data-full, and overrun error

**Figure 17.1 Block Diagram of I²C Bus Interface 2**

**Figure 17.2 External Circuit Connections of I/O Pins**

## 17.2 Input/Output Pins

Table 17.1 summarizes the input/output pins used by the I<sup>2</sup>C bus interface 2.

**Table 17.1 I<sup>2</sup>C Bus Interface Pins**

| Name         | Abbreviation | I/O | Function                      |
|--------------|--------------|-----|-------------------------------|
| Serial clock | SCL          | I/O | IIC serial clock input/output |
| Serial data  | SDA          | I/O | IIC serial data input/output  |

## 17.3 Register Descriptions

The I<sup>2</sup>C bus interface 2 has the following registers:

- I<sup>2</sup>C bus control register 1 (ICCR1)
- I<sup>2</sup>C bus control register 2 (ICCR2)
- I<sup>2</sup>C bus mode register (ICMR)
- I<sup>2</sup>C bus interrupt enable register (ICIER)
- I<sup>2</sup>C bus status register (ICSR)
- I<sup>2</sup>C bus slave address register (SAR)
- I<sup>2</sup>C bus transmit data register (ICDRT)
- I<sup>2</sup>C bus receive data register (ICDRR)

- I<sup>2</sup>C bus shift register (ICDRS)

### 17.3.1 I<sup>2</sup>C Bus Control Register 1 (ICCR1)

ICCR1 enables or disables the I<sup>2</sup>C bus interface 2, controls transmission or reception, and selects master or slave mode, transmission or reception, and transfer clock frequency in master mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 17.3.2 I<sup>2</sup>C Bus Control Register 2 (ICCR2)

ICCR1 issues start/stop conditions, manipulates the SDA pin, monitors the SCL pin, and controls reset in the control part of the I<sup>2</sup>C bus interface 2.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | BBSY     | 0             | R/W | <p>Bus Busy</p> <p>This bit enables to confirm whether the I<sup>2</sup>C bus is occupied or released and to issue start/stop conditions in master mode. With the clocked synchronous serial format, this bit has no meaning. With the I<sup>2</sup>C bus format, this bit is set to 1 when the SDA level changes from high to low under the condition of SCL = high, assuming that the start condition has been issued. This bit is cleared to 0 when the SDA level changes from low to high under the condition of SCL = high, assuming that the stop condition has been issued. Write 1 to BBSY and 0 to SCP to issue a start condition. Follow this procedure when also re-transmitting a start condition. Write 0 in BBSY and 0 in SCP to issue a stop condition. To issue start/stop conditions, use the MOV instruction.</p> |
| 6   | SCP      | 1             | W   | <p>Start/Stop Issue Condition Disable</p> <p>The SCP bit controls the issue of start/stop conditions in master mode.</p> <p>To issue a start condition, write 1 in BBSY and 0 in SCP. A retransmit start condition is issued in the same way. To issue a stop condition, write 0 in BBSY and 0 in SCP. This bit is always read as 1. If 1 is written, the data is not stored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 5   | SDAO     | 1             | R/W | <p>SDA Output Value Control</p> <p>This bit is used with SDAOP when modifying output level of SDA. This bit should not be manipulated during transfer.</p> <p>0: When reading, SDA pin outputs low.<br/>When writing, SDA pin is changed to output low.</p> <p>1: When reading, SDA pin outputs high.<br/>When writing, SDA pin is changed to output Hi-Z (outputs high by external pull-up resistance).</p>                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                        |
|-----|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | SDAOP    | 1             | R/W | SDAO Write Protect<br><br>This bit controls change of output level of the SDA pin by modifying the SDAO bit. To change the output level, clear SDAO and SDAOP to 0 or set SDAO to 1 and clear SDAOP to 0 by the MOV instruction. This bit is always read as 1.                                                     |
| 3   | SCLO     | 1             | R   | This bit monitors SCL output level. When SCLO is 1, SCL pin outputs high. When SCLO is 0, SCL pin outputs low.                                                                                                                                                                                                     |
| 2   | —        | 1             | —   | Reserved<br><br>This bit is always read as 1, and cannot be modified.                                                                                                                                                                                                                                              |
| 1   | IICRST   | 0             | R/W | IIC Control Part Reset<br><br>This bit resets the control part except for I <sup>2</sup> C registers. If this bit is set to 1 when hang-up occurs because of communication failure during I <sup>2</sup> C operation, I <sup>2</sup> C control part can be reset without setting ports and initializing registers. |
| 0   | —        | 1             | —   | Reserved<br><br>This bit is always read as 1, and cannot be modified.                                                                                                                                                                                                                                              |

### 17.3.3 I<sup>2</sup>C Bus Mode Register (ICMR)

ICMR selects whether the MSB or LSB is transferred first, performs master mode wait control, and selects the transfer bit count.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 1                           | BC1                             | 0             | R/W | These bits specify the number of bits to be transferred next. When read, the remaining number of transfer bits is indicated. With the I <sup>2</sup> C bus format, the data is transferred with one addition acknowledge bit. Bit BC2 to BC0 settings should be made during an interval between transfer frames. If bits BC2 to BC0 are set to a value other than 000, the setting should be made while the SCL pin is low. The value returns to 000 at the end of a data transfer, including the acknowledge bit. With the clock synchronous serial format, these bits should not be modified.<br><br><table><thead><tr><th>I<sup>2</sup>C Bus Format</th><th>Clock Synchronous Serial Format</th></tr></thead><tbody><tr><td>000: 9 bits</td><td>000: 8 bits</td></tr><tr><td>001: 2 bits</td><td>001: 1 bits</td></tr><tr><td>010: 3 bits</td><td>010: 2 bits</td></tr><tr><td>011: 4 bits</td><td>011: 3 bits</td></tr><tr><td>100: 5 bits</td><td>100: 4 bits</td></tr><tr><td>101: 6 bits</td><td>101: 5 bits</td></tr><tr><td>110: 7 bits</td><td>110: 6 bits</td></tr><tr><td>111: 8 bits</td><td>111: 7 bits</td></tr></tbody></table> | I <sup>2</sup> C Bus Format | Clock Synchronous Serial Format | 000: 9 bits | 000: 8 bits | 001: 2 bits | 001: 1 bits | 010: 3 bits | 010: 2 bits | 011: 4 bits | 011: 3 bits | 100: 5 bits | 100: 4 bits | 101: 6 bits | 101: 5 bits | 110: 7 bits | 110: 6 bits | 111: 8 bits | 111: 7 bits |

### 17.3.4 I<sup>2</sup>C Bus Interrupt Enable Register (ICIER)

ICIER enables or disables interrupt sources and acknowledge bits, sets acknowledge bits to be transferred, and confirms acknowledge bits to be received.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 17.3.6 Slave Address Register (SAR)

SAR selects the communication format and sets the slave address. When the chip is in slave mode with the I<sup>2</sup>C bus format, if the upper 7 bits of SAR match the upper 7 bits of the first frame received after a start condition, the chip operates as the slave device.

| Bit    | Bit Name     | Initial Value | R/W | Description                                                                                                                                                                       |
|--------|--------------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 1 | SVA6 to SVA0 | All 0         | R/W | <p>Slave Address 6 to 0</p> <p>These bits set a unique address in bits SVA6 to SVA0, differing from the addresses of other slave devices connected to the I<sup>2</sup>C bus.</p> |
| 0      | FS           | 0             | R/W | <p>Format Select</p> <p>0: I<sup>2</sup>C bus format is selected.</p> <p>1: Clocked synchronous serial format is selected.</p>                                                    |

### 17.3.7 I<sup>2</sup>C Bus Transmit Data Register (ICDRT)

ICDRT is an 8-bit readable/writable register that stores the transmit data. When ICDRT detects the space in the shift register (ICDRS), it transfers the transmit data which is written in ICDRT to ICDRS and starts transferring data. If the next transfer data is written to ICDRT during transferring data of ICDRS, continuous transfer is possible. If the MLS bit of ICMR is set to 1 and when the data is written to ICDRT, the MSB/LSB inverted data is read. The initial value of ICDRT is H'FF.

### 17.3.8 I<sup>2</sup>C Bus Receive Data Register (ICDRR)

ICDRR is an 8-bit register that stores the receive data. When data of one byte is received, ICDRR transfers the receive data from ICDRS to ICDRR and the next data can be received. ICDRR is a receive-only register, therefore the CPU cannot write to this register. The initial value of ICDRR is H'FF.

### 17.3.9 I<sup>2</sup>C Bus Shift Register (ICDRS)

ICDRS is a register that is used to transfer/receive data. In transmission, data is transferred from ICDRT to ICDRS and the data is sent from the SDA pin. In reception, data is transferred from ICDRS to ICDRR after data of one byte is received. This register cannot be read directly from the CPU.

## 17.4 Operation

The I<sup>2</sup>C bus interface can communicate either in I<sup>2</sup>C bus mode or clocked synchronous serial mode by setting FS in SAR.

### 17.4.1 I<sup>2</sup>C Bus Format

Figure 17.3 shows the I<sup>2</sup>C bus formats. Figure 17.4 shows the I<sup>2</sup>C bus timing. The first frame following a start condition always consists of 8 bits.

**Figure 17.3 I<sup>2</sup>C Bus Formats**

**Figure 17.4 I<sup>2</sup>C Bus Timing**

### Legend

- S: Start condition. The master device drives SDA from high to low while SCL is high.
- SLA: Slave address
- R/W: Indicates the direction of data transfer: from the slave device to the master device when  $\overline{R/W}$  is 1, or from the master device to the slave device when  $\overline{R/W}$  is 0.
- A: Acknowledge. The receive device drives SDA to low.
- DATA: Transfer data

P: Stop condition. The master device drives SDA from low to high while SCL is high.

### 17.4.2 Master Transmit Operation

In master transmit mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For master transmit mode operation timing, refer to figures 17.5 and 17.6. The transmission procedure and operations in master transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MLS and WAIT bits in ICMR and the CKS3 to CKS0 bits in ICCR1 to 1. (Initial setting)
2. Read the BBSY flag in ICCR2 to confirm that the bus is free. Set the MST and TRS bits in ICCR1 to select master transmit mode. Then, write 1 to BBSY and 0 to SCP using MOV instruction. (Start condition issued) This generates the start condition.
3. After confirming that TDRE in ICSR has been set, write the transmit data (the first byte data show the slave address and  $R/\overline{W}$ ) to ICDRT. At this time, TDRE is automatically cleared to 0, and data is transferred from ICDRT to ICDRS. TDRE is set again.
4. When transmission of one byte data is completed while TDRE is 1, TEND in ICSR is set to 1 at the rise of the 9th transmit clock pulse. Read the ACKBR bit in ICIER, and confirm that the slave device has been selected. Then, write second byte data to ICDRT. When ACKBR is 1, the slave device has not been acknowledged, so issue the stop condition. To issue the stop condition, write 0 to BBSY and SCP using MOV instruction. SCL is fixed low until the transmit data is prepared or the stop condition is issued.
5. The transmit data after the second byte is written to ICDRT every time TDRE is set.
6. Write the number of bytes to be transmitted to ICDRT. Wait until TEND is set (the end of last byte data transmission) while TDRE is 1, or wait for NACK (NACKF in ICSR = 1) from the receive device while ACKF in ICIER is 1. Then, issue the stop condition to clear TEND or NACKF.
7. When the STOP bit in ICSR is set to 1, the operation returns to the slave receive mode.

**Figure 17.5 Master Transmit Mode Operation Timing (1)**

**Figure 17.6 Master Transmit Mode Operation Timing (2)**

### 17.4.3 Master Receive Operation

In master receive mode, the master device outputs the receive clock, receives data from the slave device, and returns an acknowledge signal. For master receive mode operation timing, refer to figures 17.7 and 17.8. The reception procedure and operations in master receive mode are shown below.

1. Clear the TEND bit in ICSR to 0, then clear the TRS bit in ICCR1 to 0 to switch from master transmit mode to master receive mode. Then, clear the TDRE bit to 0.
2. When ICDRR is read (dummy data read), reception is started, and the receive clock is output, and data received, in synchronization with the internal clock. The master device outputs the level specified by ACKBT in ICIER to SDA, at the 9th receive clock pulse.
3. After the reception of first frame data is completed, the RDRF bit in ICST is set to 1 at the rise of 9th receive clock pulse. At this time, the receive data is read by reading ICDRR, and RDRF is cleared to 0.
4. The continuous reception is performed by reading ICDRR every time RDRF is set. If 8th receive clock pulse falls after reading ICDRR by the other processing while RDRF is 1, SCL is fixed low until ICDRR is read.
5. If next frame is the last receive data, set the RCVD bit in ICCR1 to 1 before reading ICDRR. This enables the issuance of the stop condition after the next reception.
6. When the RDRF bit is set to 1 at rise of the 9th receive clock pulse, issue the stage condition.
7. When the STOP bit in ICSR is set to 1, read ICDRR. Then clear the RCVD bit to 0.
8. The operation returns to the slave receive mode.

**Figure 17.7 Master Receive Mode Operation Timing (1)**

**Figure 17.8 Master Receive Mode Operation Timing (2)**

#### 17.4.4 Slave Transmit Operation

In slave transmit mode, the slave device outputs the transmit data, while the master device outputs the receive clock and returns an acknowledge signal. For slave transmit mode operation timing, refer to figures 17.9 and 17.10.

The transmission procedure and operations in slave transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MLS and WAIT bits in ICMR and the CKS3 to CKS0 bits in ICCR1 to 1. (Initial setting) Set the MST and TRS bits in ICCR1 to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At this time, if the 8th bit data ( $\overline{R/W}$ ) is 1, the TRS and ICSR bits in ICCR1 are set to 1, and the mode changes to slave transmit mode automatically. The continuous transmission is performed by writing transmit data to ICDRT every time TDRE is set.
3. If TDRE is set after writing last transmit data to ICDRT, wait until TEND in ICSR is set to 1, with TDRE = 1. When TEND is set, clear TEND.
4. Clear TRS for the end processing, and read ICDRR (dummy read). SCL is free.
5. Clear TDRE.

**Figure 17.9 Slave Transmit Mode Operation Timing (1)**

**Figure 17.10 Slave Transmit Mode Operation Timing (2)**

### 17.4.5 Slave Receive Operation

In slave receive mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For slave receive mode operation timing, refer to figures 17.11 and 17.12. The reception procedure and operations in slave receive mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MLS and WAIT bits in ICMR and the CKS3 to CKS0 bits in ICCR1 to 1. (Initial setting) Set the MST and TRS bits in ICCR1 to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At the same time, RDRF in ICSR is set to read ICDRR (dummy read). (Since the read data show the slave address and R/W, it is not used.)
3. Read ICDRR every time RDRF is set. If 8th receive clock pulse falls while RDRF is 1, SCL is fixed low until ICDRR is read. The change of the acknowledge before reading ICDRR, to be returned to the master device, is reflected to the next transmit frame.

4. The last byte data is read by reading ICDRR.

**Figure 17.11 Slave Receive Mode Operation Timing (1)**

**Figure 17.12 Slave Receive Mode Operation Timing (2)**

## 17.4.6 Clocked Synchronous Serial Format

This module can be operated with the clocked synchronous serial format, by setting the FS bit in SAR to 1. When the MST bit in ICCR1 is 1, the transfer clock output from SCL is selected. When MST is 0, the external clock input is selected.

### Data Transfer Format

Figure 17.13 shows the clocked synchronous serial transfer format.

The transfer data is output from the rise to the fall of the SCL clock, and the data at the rising edge of the SCL clock is guaranteed. The MLS bit in ICMR sets the order of data transfer, in either the MSB first or LSB first. The output level of SDA can be changed during the transfer wait, by the SDAO bit in ICCR2.

**Figure 17.13 Clocked Synchronous Serial Transfer Format**

### Transmit Operation

In transmit mode, transmit data is output from SDA, in synchronization with the fall of the transfer clock. The transfer clock is output when MST in ICCR1 is 1, and is input when MST is 0. For transmit mode operation timing, refer to figure 17.14. The transmission procedure and operations in transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MST and CKS3 to CKS0 bits in ICCR1 to 1. (Initial setting)
2. Set the TRS bit in ICCR1 to select the transmit mode. Then, TDRE in ICSR is set.
3. Confirm that TDRE has been set. Then, write the transmit data to ICDRT. The data is transferred from ICDRT to ICDRS, and TDRE is set automatically. The continuous transmission is performed by writing data to ICDRT every time TDRE is set. When changing from transmit mode to receive mode, clear TRS while TDRE is 1.

**Figure 17.14 Transmit Mode Operation Timing**

## Receive Operation

In receive mode, data is latched at the rise of the transfer clock. The transfer clock is output when MST in ICCR1 is 1, and is input when MST is 0. For receive mode operation timing, refer to figure 17.15. The reception procedure and operations in receive mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MST and CKS3 to CKS0 bits in ICCR1 to 1. (Initial setting)
2. When the transfer clock is output, set MST to 1 to start outputting the receive clock.
3. When the receive operation is completed, data is transferred from ICDRS to ICDRR and RDRF in ICSR is set. When MST = 1, the next byte can be received, so the clock is continually output. The continuous reception is performed by reading ICDRR every time RDRF is set. When the 8th clock is risen while RDRF is 1, the overrun is detected and AL/OVE in ICSR is set. At this time, the previous reception data is retained in ICDRR.
4. To stop receiving when MST = 1, set RCVD in ICCR1 to 1, then read ICDRR. Then, SCL is fixed high after receiving the next byte data.

**Figure 17.15 Receive Mode Operation Timing**

### 17.4.7 Noise Canceler

The logic levels at the SCL and SDA pins are routed through noise cancelers before being latched internally. Figure 17.16 shows a block diagram of the noise canceler circuit.

The noise canceler consists of two cascaded latches and a match detector. The SCL (or SDA) input signal is sampled on the system clock, but is not passed forward to the next circuit unless the outputs of both latches agree. If they do not agree, the previous value is held.

**Figure 17.16 Block Diagram of Noise Canceler**

## 17.4.8 Example of Use

Flowcharts in respective modes that use the I<sup>2</sup>C bus interface are shown in figures 17.17 to 17.20.

Figure 17.17 Sample Flowchart for Master Transmit Mode

**Figure 17.18 Sample Flowchart for Master Receive Mode**

- [1] Clear the AAS flag.
- [2] Set transmit data for ICDRT (except for the last data).
- [3] Wait for ICDRT empty.
- [4] Set the last byte of transmit data.
- [5] Wait for the last byte to be transmitted.
- [6] Clear the TEND flag .
- [7] Set slave receive mode.
- [8] Dummy-read ICDRR to release the SCL line.
- [9] Clear the TDRE flag.

**Figure 17.19 Sample Flowchart for Slave Transmit Mode**

**Figure 17.20 Sample Flowchart for Slave Receive Mode**

## 17.5 Interrupt Request

There are six interrupt requests in this module; transmit data empty, transmit end, receive data full, NACK receive, STOP recognition, and arbitration lost/overrun error. Table 17.3 shows the contents of each interrupt request.

**Table 17.3 Interrupt Requests**

| Interrupt Request                 | Abbreviation | Interrupt Condition  | I <sup>2</sup> C Mode | Clocked Synchronous Mode |
|-----------------------------------|--------------|----------------------|-----------------------|--------------------------|
| Transmit Data Empty               | TXI          | (TDRE=1) • (TIE=1)   | ○                     | ○                        |
| Transmit End                      | TEI          | (TEND=1) • (TEIE=1)  | ○                     | ○                        |
| Receive Data Full                 | RXI          | (RDRF=1) • (RIE=1)   | ○                     | ○                        |
| STOP Recognition                  | STPI         | (STOP=1) • (STIE=1)  | ○                     | ×                        |
| NACK Receive                      | NAKI         | {(NACKF=1)+(AL=1)} • | ○                     | ×                        |
| Arbitration<br>Lost/Overrun Error |              | (NAKIE=1)            | ○                     | ○                        |

When interrupt conditions described in table 17.3 are 1 and the I bit in CCR is 0, the CPU executes an interrupt exception processing. Interrupt sources should be cleared in the exception processing. TDRE and TEND are automatically cleared to 0 by writing the transmit data to ICDRT. RDRF are automatically cleared to 0 by reading ICDRR. TDRE is set to 1 again at the same time when transmit data is written to ICDRT. When TDRE is cleared to 0, then an excessive data of one byte may be transmitted.

# 17.6 Bit Synchronous Circuit

In master mode, this module has a possibility that high level period may be short in the two states described below.

- When SCL is driven to low by the slave device
- When the rising speed of SCL is lowered by the load of the SCL line (load capacitance or pull-up resistance)

Therefore, it monitors SCL and communicates by bit with synchronization.

Figure 17.21 shows the timing of the bit synchronous circuit and table 17.4 shows the time when SCL output changes from low to Hi-Z then SCL is monitored.

Figure 17.21 The Timing of the Bit Synchronous Circuit

Table 17.4 Time for Monitoring SCL

| CKS3 | CKS2 | Time for Monitoring SCL |
|------|------|-------------------------|
| 0    | 0    | 7.5 tcyc                |
|      | 1    | 19.5 tcyc               |
| 1    | 0    | 17.5 tcyc               |
|      | 1    | 41.5 tcyc               |

## Section 18 A/D Converter

This LSI includes a successive approximation type 10-bit A/D converter that allows up to eight analog input channels to be selected. The block diagram of the A/D converter is shown in figure 18.1.

### 18.1 Features

- 10-bit resolution
- Eight input channels
- Conversion time: at least 3.5  $\mu$ s per channel (at 20-MHz operation)
- Two operating modes
  - Single mode: Single-channel A/D conversion
  - Scan mode: Continuous A/D conversion on 1 to 4 channels
- Four data registers
  - Conversion results are held in a data register for each channel
- Sample-and-hold function
- Two conversion start methods
  - Software
  - External trigger signal
- Interrupt request
  - An A/D conversion end interrupt request (ADI) can be generated

#### Legend

ADCR : A/D control register  
 ADCSR : A/D control/status register  
 ADDR A : A/D data register A  
 ADDR B : A/D data register B  
 ADDR C : A/D data register C  
 ADDR D : A/D data register D

**Figure 18.1 Block Diagram of A/D Converter**

## 18.2 Input/Output Pins

Table 18.1 summarizes the input pins used by the A/D converter. The 8 analog input pins are divided into two groups; analog input pins 0 to 3 (AN0 to AN3) comprising group 0, analog input pins 4 to 7 (AN4 to AN7) comprising group 1. The AV<sub>cc</sub> pin is the power supply pin for the analog block in the A/D converter.

**Table 18.1 Pin Configuration**

| Pin Name                       | Abbreviation     | I/O   | Function                                           |
|--------------------------------|------------------|-------|----------------------------------------------------|
| Analog power supply pin        | AV <sub>cc</sub> | Input | Analog block power supply                          |
| Analog input pin 0             | AN0              | Input | Group 0 analog input                               |
| Analog input pin 1             | AN1              | Input |                                                    |
| Analog input pin 2             | AN2              | Input |                                                    |
| Analog input pin 3             | AN3              | Input |                                                    |
| Analog input pin 4             | AN4              | Input | Group 1 analog input                               |
| Analog input pin 5             | AN5              | Input |                                                    |
| Analog input pin 6             | AN6              | Input |                                                    |
| Analog input pin 7             | AN7              | Input |                                                    |
| A/D external trigger input pin | ADTRG            | Input | External trigger input for starting A/D conversion |

## 18.3 Register Descriptions

The A/D converter has the following registers.

- A/D data register A (ADDRA)
- A/D data register B (ADDRB)
- A/D data register C (ADDRC)
- A/D data register D (ADDRD)
- A/D control/status register (ADCSR)
- A/D control register (ADCR)

### 18.3.1 A/D Data Registers A to D (ADDRA to ADDRD)

There are four 16-bit read-only ADDR registers; ADDRA to ADDRD, used to store the results of A/D conversion. The ADDR registers, which store a conversion result for each analog input channel, are shown in table 18.2.

The converted 10-bit data is stored in bits 15 to 6. The lower 6 bits are always read as 0.

The data bus width between the CPU and the A/D converter is 8 bits. The upper byte can be read directly from the CPU, however the lower byte should be read via a temporary register. The temporary register contents are transferred from the ADDR when the upper byte data is read. When reading ADDR, read the upper bytes only or read in word units. ADDR is initialized to H'0000.

**Table 18.2 Analog Input Channels and Corresponding ADDR Registers**

| Analog Input Channel |         |                                                          |
|----------------------|---------|----------------------------------------------------------|
| Group 0              | Group 1 | A/D Data Register to Be Stored Results of A/D Conversion |
| AN0                  | AN4     | ADDRA                                                    |
| AN1                  | AN5     | ADDRB                                                    |
| AN2                  | AN6     | ADDRC                                                    |
| AN3                  | AN7     | ADDRD                                                    |

### 18.3.2 A/D Control/Status Register (ADCSR)

ADCSR consists of the control bits and conversion end status bits of the A/D converter.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                            |
|-----|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | ADF      | 0             | R/W | A/D End Flag<br>[Setting conditions] <ul style="list-style-type: none"><li>• When A/D conversion ends in single mode</li><li>• When A/D conversion ends once on all the channels selected in scan mode</li></ul> [Clearing condition] <ul style="list-style-type: none"><li>• When 0 is written after reading ADF = 1</li></ul>        |
| 6   | ADIE     | 0             | R/W | A/D Interrupt Enable<br>A/D conversion end interrupt request (ADI) is enabled by ADF when this bit is set to 1                                                                                                                                                                                                                         |
| 5   | ADST     | 0             | R/W | A/D Start<br>Setting this bit to 1 starts A/D conversion. |     |          |               |     | When SCAN = 1                 |
|     |          |               |     | 000: AN0                      |
|     |          |               |     | 000: AN0                      |
|     |          |               |     | 001: AN1                      |
|     |          |               |     | 001: AN0 and AN1              |
|     |          |               |     | 010: AN2                      |
|     |          |               |     | 010: AN0 to AN2               |
|     |          |               |     | 011: AN3                      |
|     |          |               |     | 011: AN0 to AN3               |
|     |          |               |     | 100: AN4                      |
|     |          |               |     | 100: AN4                      |
|     |          |               |     | 101: AN5                      |
|     |          |               |     | 101: AN4 and AN5              |
|     |          |               |     | 110: AN6                      |
|     |          |               |     | 110: AN4 to AN6               |
|     |          |               |     | 111: AN7                      |
|     |          |               |     | 111: AN4 to AN7               |

### 18.3.3 A/D Control Register (ADCR)

ADCR enables A/D conversion started by an external trigger signal.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                |
|--------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | TRGE     | 0             | R/W | Trigger Enable                                                                                                                                                                             |
|        |          |               |     | A/D conversion is started at the falling edge and the rising edge of the external trigger signal ( $\overline{\text{ADTRG}}$ ) when this bit is set to 1.                                  |
|        |          |               |     | The selection between the falling edge and rising edge of the external trigger pin ( $\overline{\text{ADTRG}}$ ) conforms to the WPEG5 bit in the interrupt edge select register 2 (IEGR2) |
| 6 to 1 | —        | All 1         | —   | Reserved                                                                                                                                                                                   |
|        |          |               |     | These bits are always read as 1.                                                                                                                                                           |
| 0      | —        | 0             | R/W | Reserved                                                                                                                                                                                   |
|        |          |               |     | Do not set this bit to 1, though the bit is readable/writable.                                                                                                                             |

## 18.4 Operation

The A/D converter operates by successive approximation with 10-bit resolution. It has two operating modes; single mode and scan mode. When changing the operating mode or analog input channel, in order to prevent incorrect operation, first clear the bit ADST in ADCSR to 0. The ADST bit can be set at the same time as the operating mode or analog input channel is changed.

### 18.4.1 Single Mode

In single mode, A/D conversion is performed once for the analog input of the specified single channel as follows:

1. A/D conversion is started when the ADST bit in ADCSR is set to 1, according to software or external trigger input.
2. When A/D conversion is completed, the result is transferred to the corresponding A/D data register of the channel.
3. On completion of conversion, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
4. The ADST bit remains set to 1 during A/D conversion. When A/D conversion ends, the ADST bit is automatically cleared to 0 and the A/D converter enters the wait state.

### 18.4.2 Scan Mode

In scan mode, A/D conversion is performed sequentially for the analog input of the specified channels (four channels maximum) as follows:

1. When the ADST bit in ADCSR is set to 1 by software or external trigger input, A/D conversion starts on the first channel in the group (AN0 when CH2 = 0, AN4 when CH2 = 1).
2. When A/D conversion for each channel is completed, the result is sequentially transferred to the A/D data register corresponding to each channel.
3. When conversion of all the selected channels is completed, the ADF flag in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt requested is generated. A/D conversion starts again on the first channel in the group.
4. The ADST bit is not automatically cleared to 0. Steps [2] and [3] are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops.

### 18.4.3 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input when the A/D conversion start delay time ( $t_D$ ) has passed after the ADST bit is set to 1, then starts conversion. Figure 18.2 shows the A/D conversion timing. Table 18.3 shows the A/D conversion time.

As indicated in figure 18.2, the A/D conversion time includes  $t_D$  and the input sampling time. The length of  $t_D$  varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in table 18.3.

In scan mode, the values given in table 18.3 apply to the first conversion time. In the second and subsequent conversions, the conversion time is 128 states (fixed) when CKS = 0 and 66 states (fixed) when CKS = 1.

**Figure 18.2 A/D Conversion Timing**

**Table 18.3 A/D Conversion Time (Single Mode)**

| Item                            | Symbol     | CKS = 0 |     |     | CKS = 1 |     |     |
|---------------------------------|------------|---------|-----|-----|---------|-----|-----|
|                                 |            | Min     | Typ | Max | Min     | Typ | Max |
| A/D conversion start delay time | $t_D$      | 6       | —   | 9   | 4       | —   | 5   |
| Input sampling time             | $t_{SPL}$  | —       | 31  | —   | —       | 15  | —   |
| A/D conversion time             | $t_{CONV}$ | 131     | —   | 134 | 69      | —   | 70  |

Note: All values represent the number of states.

#### 18.4.4 External Trigger Input Timing

A/D conversion can also be started by an external trigger input. When the TRGE bit in ADCR is set to 1, external trigger input is enabled at the  $\overline{ADTRG}$  pin. A falling edge at the  $\overline{ADTRG}$  input pin sets the ADST bit in ADCSR to 1, starting A/D conversion. Other operations, in both single and scan modes, are the same as when the bit ADST has been set to 1 by software. Figure 18.3 shows the timing.

**Figure 18.3 External Trigger Input Timing**

## 18.5 A/D Conversion Accuracy Definitions

This LSI's A/D conversion accuracy definitions are given below.

- **Resolution**  
The number of A/D converter digital output codes
- **Quantization error**  
The deviation inherent in the A/D converter, given by 1/2 LSB (see figure 18.4).
- **Offset error**  
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from the minimum voltage value 0000000000 to 0000000001 (see figure 18.5).
- **Full-scale error**  
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from 1111111110 to 1111111111 (see figure 18.5).
- **Nonlinearity error**  
The deviation from the ideal A/D conversion characteristic as the voltage changes from zero to full scale. This does not include the offset error, full-scale error, or quantization error.
- **Absolute accuracy**  
The deviation between the digital value and the analog input value. Includes offset error, full-scale error, quantization error, and nonlinearity error.

**Figure 18.4 A/D Conversion Accuracy Definitions (1)**

**Figure 18.5 A/D Conversion Accuracy Definitions (2)**

## 18.6 Usage Notes

### 18.6.1 Permissible Signal Source Impedance

This LSI's analog input is designed such that conversion accuracy is guaranteed for an input signal for which the signal source impedance is 5 k $\Omega$  or less. This specification is provided to enable the A/D converter's sample-and-hold circuit input capacitance to be charged within the sampling time; if the sensor output impedance exceeds 5 k $\Omega$ , charging may be insufficient and it may not be possible to guarantee A/D conversion accuracy. However, for A/D conversion in single mode with a large capacitance provided externally, the input load will essentially comprise only the internal input resistance of 10 k $\Omega$ , and the signal source impedance is ignored. However, as a low-pass filter effect is obtained in this case, it may not be possible to follow an analog signal with a large differential coefficient (e.g., 5 mV/ $\mu$ s or greater) (see figure 18.6). When converting a high-speed analog signal or converting in scan mode, a low-impedance buffer should be inserted.

### 18.6.2 Influences on Absolute Accuracy

Adding capacitance results in coupling with GND, and therefore noise in GND may adversely affect absolute accuracy. Be sure to make the connection to an electrically stable GND.

Care is also required to ensure that filter circuits do not interfere with digital signals or act as antennas on the mounting board.

**Figure 18.6 Analog Input Circuit Example**

## Section 19 EEPROM

The H8/3687N has an on-chip 512-byte EEPROM. The block diagram of the EEPROM is shown in figure 19.1.

### 19.1 Features

- Two writing methods:
  - 1-byte write
  - Page write: Page size 8 bytes
- Three reading methods:
  - Current address read
  - Random address read
  - Sequential read
- Acknowledge polling possible
- Write cycle time:
  - 10 ms (power supply voltage  $V_{cc} = 2.7\text{ V}$  or more)
- Write/Erase endurance:
  - $10^4$  cycles/byte (byte write mode),  $10^5$  cycles/page (page write mode)
- Data retention:
  - 10 years after the write cycle of  $10^4$  cycles (page write mode)
- Interface with the CPU
  - I<sup>2</sup>C bus interface (complies with the standard of Philips Corporation)
  - Device code 1010
  - Sleep address code can be changed (initial value: 000)
  - The I<sup>2</sup>C bus is open to the outside, so the EEPROM can be directly accessed from the outside.

Legend: ESAR: Register for referring the slave address  
(specifies the slave address of the memory array)

**Figure 19.1 Block Diagram of EEPROM**

## 19.2 Input/Output Pins

Pins used in the EEPROM are listed in table 19.1.

**Table 19.1 Pin Configuration**

| Pin name         | Symbol | Input/Output | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Serial clock pin | SCL    | Input        | The SCL pin is used to control serial input/output data timing. The data is input at the rising edge of the clock and output at the falling edge of the clock. The SCL pin needs to be pulled up by resistor as that pin is open-drain driven structure of the I <sup>2</sup> C pin. Use proper resistor value for your system by considering $V_{OL}$ , $I_{OL}$ , and the $C_{IN}$ pin capacitance in section 23.2.2, DC Characteristics and in section 23.2.3, AC Characteristics. Maximum clock frequency is 400 kHz.     |
| Serial data pin  | SDA    | Input/Output | The SDA pin is bidirectional for serial data transfer. The SDA pin needs to be pulled up by resistor as that pin is open-drain driven structure. Use proper resistor value for your system by considering $V_{OL}$ , $I_{OL}$ , and the $C_{IN}$ pin capacitance in section 23.2.2, DC Characteristics and in section 23.2.3, AC Characteristics. Except for a start condition and a stop condition which will be discussed later, the high-to-low and low-to-high change of SDA input should be done during SCL low periods. |

## 19.3 Register Description

The EEPROM has a following register.

- EEPROM key register (EKR)

### 19.3.1 EEPROM Key Register (EKR)

EKR is an 8-bit readable/writable register, which changes the slave address code written in the EEPROM. The slave address code is changed by writing H'5F in EKR and then writing either of H'00 to H'07 as an address code to the H'FF09 address in the EEPROM by the byte write method. EKR is initialized to H'FF.

## 19.4 Operation

### 19.4.1 EEPROM Interface

The HD64N3687G has a multi-chip structure with two internal chips of the HD64F3687G (F-ZTAT™ version) and 512-byte EEPROM. The HD6483687G has a multi-chip structure with two internal chips of the HD6433687G (mask-ROM version) and 512-byte EEPROM.

The EEPROM interface is the I<sup>2</sup>C bus interface. This I<sup>2</sup>C bus is open to the outside, so the communication with the external devices connected to the I<sup>2</sup>C bus can be made.

### 19.4.2 Bus Format and Timing

The I<sup>2</sup>C bus format and the I<sup>2</sup>C bus timing follow section 17.4.1, I<sup>2</sup>C Bus Format. The bus formats specific for the EEPROM are the following two.

1. The EEPROM address is configured of two bytes, the write data is transferred in the order of upper address and lower address from each MSB side.
2. The write data is transmitted from the MSB side.

The bus format and bus timing of the EEPROM are shown in figure 19.2.

**Figure 19.2 EEPROM Bus Format and Bus Timing**

### 19.4.3 Start Condition

A high-to-low transition of the SDA input with the SCL input high is needed to generate the start condition for starting read, write operation.

#### 19.4.4 Stop Condition

A low-to-high transition of the SDA input with the SCL input high is needed to generate the stop condition for stopping read, write operation.

The standby operation starts after a read sequence by a stop condition. In the case of write operation, a stop condition terminates the write data inputs and place the device in an internally-timed write cycle to the memories. After the internally-timed write cycle ( $t_{wc}$ ) which is specified as  $t_{wc}$ , the device enters a standby mode.

#### 19.4.5 Acknowledge

All address data and serial data such as read data and write data are transmitted to and from in 8-bit unit. The acknowledgement is the signal that indicates that this 8-bit data is normally transmitted to and from.

In the write operation, EEPROM sends "0" to acknowledge in the ninth cycle after receiving the data. In the read operation, EEPROM sends a read data following the acknowledgement after receiving the data. After sending read data, the EEPROM enters the bus open state. If the EEPROM receives "0" as an acknowledgement, it sends read data of the next address. If the EEPROM does not receive acknowledgement "0" and receives a following stop condition, it stops the read operation and enters a standby mode. If the EEPROM receives neither acknowledgement "0" nor a stop condition, the EEPROM keeps bus open without sending read data.

#### 19.4.6 Slave Addressing

The EEPROM device receives a 7-bit slave address and a 1-bit  $\overline{R/\overline{W}}$  code following the generation of the start conditions. The EEPROM enables the chip for a read or a write operation with this operation.

The slave address consists of a former 4-bit device code and latter 3-bit slave address as shown in table 19.2. The device code is used to distinguish device type and this LSI uses "1010" fixed code in the same manner as in a general-purpose EEPROM. The slave address code selects one device out of all devices with device code 1010 (8 devices in maximum) which are connected to the I<sup>2</sup>C bus. This means that the device is selected if the inputted slave address code received in the order of A2, A1, A0 is equal to the corresponding slave address reference register (ESAR).

The slave address code is stored in the address H'FF09 in the EEPROM. It is transferred to ESAR from the slave address register in the memory array during 10 ms after the reset is released. An access to the EEPROM is not allowed during transfer.

The initial value of the slave address code written in the EEPROM is H'00. It can be written in the range of H'00 to H'07. Be sure to write the data by the byte write method.

The next one bit of the slave address is the  $\overline{R/\overline{W}}$  code. 0 is for a write and 1 is for a read.

The EEPROM turns to a standby state if the device code is not "1010" or slave address code doesn't coincide.

**Table 19.2 Slave Addresses**

| Bit | Bit name              | Initial Value | Setting Value | Remarks                          |
|-----|-----------------------|---------------|---------------|----------------------------------|
| 7   | Device code D3        | —             | 1             |                                  |
| 6   | Device code D2        | —             | 0             |                                  |
| 5   | Device code D1        | —             | 1             |                                  |
| 4   | Device code D0        | —             | 0             |                                  |
| 3   | Slave address code A2 | 0             | A2            | The initial value can be changed |
| 2   | Slave address code A1 | 0             | A1            | The initial value can be changed |
| 1   | Slave address code A0 | 0             | A0            | The initial value can be changed |

### 19.4.7 Write Operations

There are two types write operations; byte write operation and page write operation. To initiate the write operation, input 0 to  $\overline{R/\overline{W}}$  code following the slave address.

#### 1. Byte Write

A write operation requires an 8-bit data of a 7-bit slave address with  $\overline{R/\overline{W}}$  code = "0". Then the EEPROM sends acknowledgement "0" at the ninth bit. This enters the write mode. Then, two bytes of the memory address are received from the MSB side in the order of upper and lower. Upon receipt of one-byte memory address, the EEPROM sends acknowledgement "0" and receives a following a one-byte write data. After receipt of write data, the EEPROM sends acknowledgement "0". If the EEPROM receives a stop condition, the EEPROM enters an internally controlled write cycle and terminates receipt of SCL and SDA inputs until completion of the write cycle. The EEPROM returns to a standby mode after completion of the write cycle.

The byte write operation is shown in figure 19.3.

**Figure 19.3 Byte Write Operation**

## 2. Page Write

This LSI is capable of the page write operation which allows any number of bytes up to 8 bytes to be written in a single write cycle. The write data is input in the same sequence as the byte write in the order of a start condition, slave address + R/W code, memory address (n), and write data (Dn) with every ninth bit acknowledgement "0" output. The EEPROM enters the page write operation if the EEPROM receives more write data (Dn+1) is input instead of receiving a stop condition after receiving the write data (Dn). LSB 3 bits (A2 to A0) in the EEPROM address are automatically incremented to be the (n+1) address upon receiving write data (Dn+1). Thus the write data can be received sequentially.

Addresses in the page are incremented at each receipt of the write data and the write data can be input up to 8 bytes. If the LSB 3 bits (A2 to A0) in the EEPROM address reach the last address of the page, the address will roll over to the first address of the same page. When the address is rolled over, write data is received twice or more to the same address, however, the last received data is valid. At the receipt of the stop condition, write data reception is terminated and the write operation is entered.

The page write operation is shown in figure 19.4.

**Figure 19.4 Page Write Operation**

## 19.4.8 Acknowledge Polling

Acknowledge polling feature is used to show if the EEPROM is in an internally-timed write cycle or not. This feature is initiated by the input of the 8-bit slave address + R/W code following the start condition during an internally-timed write cycle. Acknowledge polling will operate R/W code = "0". The ninth acknowledgement judges if the EEPROM is in an internally-timed write cycle or not. Acknowledgement "1" shows the EEPROM is in a internally-timed write cycle and acknowledgement "0" shows the internally-timed write cycle has been completed. The acknowledge polling starts to function after a write data is input, i.e., when the stop condition is input.

## 19.4.9 Read Operation

There are three read operations; current address read, random address read, and sequential read. Read operations are initiated in the same way as write operations with the exception of R/W = 1.

### 1. Current Address Read

The internal address counter maintains the (n+1) address that is made by the last address (n) accessed during the last read or write operation, with incremented by one. Current address read accesses the (n+1) address kept by the internal address counter.

After receiving in the order of a start condition and the slave address +  $R/\overline{W}$  code (R/W = 1), the EEPROM outputs the 1-byte data of the (n+1) address from the most significant bit following acknowledgement "0". If the EEPROM receives in the order of acknowledgement "1" and a following stop condition, the EEPROM stops the read operation and is turned to a standby state.

In case the EEPROM has accessed the last address H'01FF at previous read operation, the current address will roll over and returns to zero address. In case the EEPROM has accessed the last address of the page at previous write operation, the current address will roll over within page addressing and returns to the first address in the same page.

The current address is valid while power is on. The current address after power on will be undefined. After power is turned on, define the address by the random address read operation described below is necessary.

The current address read operation is shown in figure 19.5.

**Figure 19.5 Current Address Read Operation**

## 2. Random Address Read

This is a read operation with defined read address. A random address read requires a dummy write to set read address. The EEPROM receives a start condition, slave address +  $\overline{\text{R/W}}$  code ( $\overline{\text{R/W}} = 0$ ), memory address (upper) and memory address (lower) sequentially. The EEPROM outputs acknowledgement "0" after receiving memory address (lower) then enters a current address read with receiving a start condition again. The EEPROM outputs the read data of the address which was defined in the dummy write operation. After receiving acknowledgement "1" and a following stop condition, the EEPROM stops the random read operation and returns to a standby state.

The random address read operation is shown in figure 19.6.

**Figure 19.6 Random Address Read Operation**

### 3. Sequential Read

This is a mode to read the data sequentially. Data is sequential read by either a current address read or a random address read. If the EEPROM receives acknowledgement "0" after 1-byte read data is output, the read address is incremented and the next 1-byte read data are coming out. Data is output sequentially by incrementing addresses as long as the EEPROM receives acknowledgement "0" after the data is output. The address will roll over and returns address zero if it reaches the last address H'01FF. The sequential read can be continued after roll over. The sequential read is terminated if the EEPROM receives acknowledgement "1" and a following stop condition as the same manner as in the random address read.

The condition of a sequential read when the current address read is used is shown in figure 19.7.

**Figure 19.7 Sequential Read Operation (when current address read is used)**

## 19.5 Usage Notes

### 19.5.1 Data Protection at $V_{CC}$ On/Off

When  $V_{CC}$  is turned on or off, the data might be destroyed by malfunction. Be careful of the notices described below to prevent the data to be destroyed.

1. SCL and SDA should be fixed to  $V_{CC}$  or  $V_{SS}$  during  $V_{CC}$  on/off.
2.  $V_{CC}$  should be turned off after the EEPROM is placed in a standby state.
3. When  $V_{CC}$  is turned on from the intermediate level, malfunction is caused, so  $V_{CC}$  should be turned on from the ground level ( $V_{SS}$ ).
4.  $V_{CC}$  turn on speed should be longer than 10  $\mu$ s.

### 19.5.2 Write/Erase Endurance

The endurance is  $10^5$  cycles/page (1% cumulative failure rate) in case of page programming and  $10^4$  cycles/byte in case of byte programming. The data retention time is more than 10 years when a device is page-programmed less than  $10^4$  cycles.

### 19.5.3 Noise Suppression Time

This EEPROM has a noise suppression function at SCL and SDA inputs, that cuts noise of width less than 50 ns. Be careful not to allow noise of width more than 50 ns because the noise of with more than 50 ms is recognized as an active pulse.

## Section 20 Power-On Reset and Low-Voltage Detection Circuits (Optional)

This LSI can include a power-on reset circuit and low-voltage detection circuit as optional circuits.

The low-voltage detection circuit consists of two circuits: LVDI (interrupt by low voltage detect) and LVDR (reset by low voltage detect) circuits.

This circuit is used to prevent abnormal operation (runaway execution) from occurring due to the power supply voltage fall and to recreate the state before the power supply voltage fall when the power supply voltage rises again.

Even if the power supply voltage falls, the unstable state when the power supply voltage falls below the guaranteed operating voltage can be removed by entering standby mode when exceeding the guaranteed operating voltage and during normal operation. Thus, system stability can be improved. If the power supply voltage falls more, the reset state is automatically entered. If the power supply voltage rises again, the reset state is held for a specified period, then active mode is automatically entered.

Figure 20.1 is a block diagram of the power-on reset circuit and the low-voltage detection circuit.

### 20.1 Features

- Power-on reset circuit  
Uses an external capacitor to generate an internal reset signal when power is first supplied.
- Low-voltage detection circuit  
LVDR: Monitors the power-supply voltage, and generates an internal reset signal when the voltage falls below a specified value.  
LVDI: Monitors the power-supply voltage, and generates an interrupt when the voltage falls below or rises above respective specified values.  
Two pairs of detection levels for reset generation voltage are available: when only the LVDR circuit is used, or when the LVDI and LVDR circuits are both used.

Note: \* Initialized by LVDR.

## 20.3 Operation

### 20.3.1 Power-On Reset Circuit

Figure 20.2 shows the timing of the operation of the power-on reset circuit. As the power-supply voltage rises, the capacitor which is externally connected to the  $\overline{\text{RES}}$  pin is gradually charged via the on-chip pull-up resistor (typ. 150 k $\Omega$ ). Since the state of the  $\overline{\text{RES}}$  pin is transmitted within the chip, the prescaler S and the entire chip are in their reset states. When the level on the  $\overline{\text{RES}}$  pin reaches the specified value, the prescaler S is released from its reset state and it starts counting. The OVF signal is generated to release the internal reset signal after the prescaler S has counted 131,072 clock ( $\phi$ ) cycles. The noise cancellation circuit of approximately 100 ns is incorporated to prevent the incorrect operation of the chip by noise on the  $\overline{\text{RES}}$  pin.

To achieve stable operation of this LSI, the power supply needs to rise to its full level and settles within the specified time. The maximum time required for the power supply to rise and settle after power has been supplied ( $t_{\text{PWON}}$ ) is determined by the oscillation frequency ( $f_{\text{OSC}}$ ) and capacitance which is connected to  $\overline{\text{RES}}$  pin ( $C_{\text{RES}}$ ). If  $t_{\text{PWON}}$  means the time required to reach 90 % of power supply voltage, the power supply circuit should be designed to satisfy the following formula.

$$t_{\text{PWON}} (\text{ms}) \leq 90 \times C_{\text{RES}} (\mu\text{F}) + 162/f_{\text{OSC}} (\text{MHz})$$

$$(t_{\text{PWON}} \leq 3000 \text{ ms}, C_{\text{RES}} \geq 0.22 \mu\text{F}, \text{ and } f_{\text{OSC}} = 10 \text{ in 2-MHz to 10-MHz operation})$$

Note that the power supply voltage ( $V_{\text{CC}}$ ) must fall below  $V_{\text{POR}} = 100 \text{ mV}$  and rise after charge on the  $\overline{\text{RES}}$  pin is removed. To remove charge on the  $\overline{\text{RES}}$  pin, it is recommended that the diode should be placed near  $V_{\text{CC}}$ . If the power supply voltage ( $V_{\text{CC}}$ ) rises from the point above  $V_{\text{POR}}$ , a power-on reset may not occur.

Figure 20.2 Operational Timing of Power-On Reset Circuit

## 20.3.2 Low-Voltage Detection Circuit

### LVDR (Reset by Low Voltage Detect) Circuit:

Figure 20.3 shows the timing of the LVDR function. The LVDR enters the module-standby state after a power-on reset is canceled. To operate the LVDR, set the LVDE bit in LVDCR to 1, wait for 50  $\mu\text{s}$  ( $t_{\text{LVDRON}}$ ) until the reference voltage and the low-voltage-detection power supply have stabilized by a software timer, etc., then set the LVDRE bit in LVDCR to 1. After that, the output settings of ports must be made. To cancel the low-voltage detection circuit, first the LVDRE bit should be cleared to 0 and then the LVDE bit should be cleared to 0. The LVDE and LVDRE bits must not be cleared to 0 simultaneously because incorrect operation may occur.

When the power-supply voltage falls below the Vreset voltage (typ. = 2.3 V or 3.6 V), the LVDR clears the  $\overline{\text{LVDRES}}$  signal to 0, and resets the prescaler S. The low-voltage detection reset state remains in place until a power-on reset is generated. When the power-supply voltage rises above the Vreset voltage again, the prescaler S starts counting. It counts 131,072 clock ( $\phi$ ) cycles, and then releases the internal reset signal. In this case, the LVDE, LVDSEL, and LVDRE bits in LVDCR are not initialized.

Note that if the power supply voltage ( $V_{\text{CC}}$ ) falls below  $V_{\text{LVDRmin}} = 1.0 \text{ V}$  and then rises from that point, the low-voltage detection reset may not occur.

If the power supply voltage ( $V_{\text{CC}}$ ) falls below  $V_{\text{por}} = 100 \text{ mV}$ , a power-on reset occurs.

Figure 20.3 Operational Timing of LVDR Circuit

## LVDI (Interrupt by Low Voltage Detect) Circuit:

Figure 20.4 shows the timing of LVDI functions. The LVDI enters the module-standby state after a power-on reset is canceled. To operate the LVDI, set the LVDE bit in LVDCR to 1, wait for 50  $\mu\text{s}$  ( $t_{\text{LVON}}$ ) until the reference voltage and the low-voltage-detection power supply have stabilized by a software timer, etc., then set the LVDDE and LVDUE bits in LVDCR to 1. After that, the output settings of ports must be made. To cancel the low-voltage detection circuit, first the LVDDE and LVDUE bits should all be cleared to 0 and then the LVDE bit should be cleared to 0. The LVDE bit must not be cleared to 0 at the same timing as the LVDDE and LVDUE bits because incorrect operation may occur.

When the power-supply voltage falls below Vint (D) (typ. = 3.7 V) voltage, the LVDI clears the  $\overline{\text{LVDINT}}$  signal to 0 and the LVDDF bit in LVDSR is set to 1. If the LVDDE bit is 1 at this time, an IRQ0 interrupt request is simultaneously generated. In this case, the necessary data must be saved in the external EEPROM, etc, and a transition must be made to standby mode or subsleep mode. Until this processing is completed, the power supply voltage must be higher than the lower limit of the guaranteed operating voltage.

When the power-supply voltage does not fall below Vreset1 (typ. = 2.3 V) voltage but rises above Vint (U) (typ. = 4.0 V) voltage, the LVDI sets the  $\overline{\text{LVDINT}}$  signal to 1. If the LVDUE bit is 1 at this time, the LVDUF bit in LVDSR is set to 1 and an IRQ0 interrupt request is simultaneously generated.

If the power supply voltage ( $V_{\text{CC}}$ ) falls below Vreset1 (typ. = 2.3 V) voltage, the LVDR function is performed.

**Figure 20.4 Operational Timing of LVDI Circuit**

## Procedures for Clearing Settings when Using LVDR and LVDI:

To operate or release the low-voltage detection circuit normally, follow the procedure described below. Figure 20.5 shows the timing for the operation and release of the low-voltage detection circuit.

1. To operate the low-voltage detection circuit, set the LVDE bit in LVDCR to 1.
2. Wait for  $50\ \mu\text{s}$  ( $t_{\text{LVDon}}$ ) until the reference voltage and the low-voltage-detection power supply have stabilized by a software timer, etc. Then, clear the LVDDF and LVDUF bits in LVDSR to 0 and set the LVDRE, LVDDE, and LVDUE bits in LVDCR to 1, as required.
3. To release the low-voltage detection circuit, start by clearing all of the LVDRE, LVDDE, and LVDUE bits to 0. Then clear the LVDE bit to 0. The LVDE bit must not be cleared to 0 at the same timing as the LVDRE, LVDDE, and LVDUE bits because incorrect operation may occur.

**Figure 20.5 Timing for Operation/Release of Low-Voltage Detection Circuit**

## Section 21 Power Supply Circuit

This LSI incorporates an internal power supply step-down circuit. Use of this circuit enables the internal power supply to be fixed at a constant level of approximately 3.0 V, independently of the voltage of the power supply connected to the external  $V_{CC}$  pin. As a result, the current consumed when an external power supply is used at 3.0 V or above can be held down to virtually the same low level as when used at approximately 3.0 V. If the external power supply is 3.0 V or below, the internal voltage will be practically the same as the external voltage. It is, of course, also possible to use the same level of external power supply voltage and internal power supply voltage without using the internal power supply step-down circuit.

### 21.1 When Using Internal Power Supply Step-Down Circuit

Connect the external power supply to the  $V_{CC}$  pin, and connect a capacitance of approximately 0.1  $\mu\text{F}$  between  $V_{CL}$  and  $V_{SS}$ , as shown in figure 21.1. The internal step-down circuit is made effective simply by adding this external circuit. In the external circuit interface, the external power supply voltage connected to  $V_{CC}$  and the GND potential connected to  $V_{SS}$  are the reference levels. For example, for port input/output levels, the  $V_{CC}$  level is the reference for the high level, and the  $V_{SS}$  level is that for the low level. The A/D converter analog power supply is not affected by the internal step-down circuit.

**Figure 21.1 Power Supply Connection when Internal Step-Down Circuit is Used**

## 21.2 When Not Using Internal Power Supply Step-Down Circuit

When the internal power supply step-down circuit is not used, connect the external power supply to the  $V_{CL}$  pin and  $V_{CC}$  pin, as shown in figure 21.2. The external power supply is then input directly to the internal power supply. The permissible range for the power supply voltage is 3.0 V to 3.6 V. Operation cannot be guaranteed if a voltage outside this range (less than 3.0 V or more than 3.6 V) is input.

**Figure 21.2 Power Supply Connection when Internal Step-Down Circuit is Not Used**

## Section 22 List of Registers

The register list gives information on the on-chip I/O register addresses, how the register bits are configured, and the register states in each operating mode. The information is given as shown below.

### 1. Register addresses (address order)

- Registers are listed from the lower allocation addresses.
- The symbol — in the register-name column represents a reserved address or range of reserved addresses.

Do not attempt to access reserved addresses.

- When the address is 16-bit wide, the address of the upper byte is given in the list.
- Registers are classified by functional modules.
- The data bus width is indicated.
- The number of access states is indicated.

### 2. Register bits

- Bit configurations of the registers are described in the same order as the register addresses.
- Reserved bits are indicated by — in the bit name column.
- When registers consist of 16 bits, bits are described from the MSB side.

### 3. Register states in each operating mode

- Register states are described in the same order as the register addresses.
- The register states described here are for the basic operating modes. If there is a specific reset for an on-chip peripheral module, refer to the section on that on-chip peripheral module.

## 22.1 Register Addresses (Address Order)

The data-bus width column indicates the number of bits. The access-state column shows the number of states of the selected basic clock that is required for access to the register.

Note: Access to undefined or reserved addresses should not take place. Correct operation of the access itself or later operations is not guaranteed when such a register is accessed.

| Register                                 | Abbreviation | Bit No | Address          | Module Name | Data Bus Width | Access State |
|------------------------------------------|--------------|--------|------------------|-------------|----------------|--------------|

Notes: 1. LVDC: Low-voltage detection circuits (optional)  
2. WDT: Watchdog timer

## 22.2 Register Bits

The addresses and bit names of the registers in the on-chip peripheral modules are listed below. The 16-bit register is indicated in two rows, 8 bits for each row.

| Register Name | Bit 7   | Bit 6   | Bit 5   | Bit 4   | Bit 3   | Bit 2   | Bit 1   | Bit 0   | Module Name |
|---------------|---------|---------|---------|---------|---------|---------|---------|---------|-------------|
| TCR_0         | CCLR2   | CCLR1   | CCLR0   | CKEG1   | CKEG0   | TPSC2   | TPSC1   | TPSC0   | Timer Z     |
| TIORA_0       | —       | IOB2    | IOB1    | IOB0    | —       | IOA2    | IOA1    | IOA0    |             |

## • EEPROM

| Register Name | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 | Module Name |
|---------------|-------|-------|-------|-------|-------|-------|-------|-------|-------------|
| EKR           |       |       |       |       |       |       |       |       | EEPROM      |

Notes: 1. LVDC: Low-voltage detection circuits (optional)

2. WDT: Watchdog timer

3. These bits are reserved in the EEPROM stacked F-ZTAT™ and mask-ROM versions.

## 22.3 Registers States in Each Operating Mode

| Register Name | Reset       | Active | Sleep | Subactive | Subsleep | Standby | Module  |

# Section 23 Electrical Characteristics

## 23.1 Absolute Maximum Ratings

**Table 23.1 Absolute Maximum Ratings**

| Item                        | Symbol                          | Value        | Unit                    | Note |
|-----------------------------|---------------------------------|--------------|-------------------------|------|
| Power supply voltage        | $V_{CC}$                        | -0.3 to +7.0 | V                       | *    |
| Analog power supply voltage | $AV_{CC}$                       | -0.3 to +7.0 | V                       |      |
| Input voltage               | Ports other than ports B and X1 | $V_{IN}$     | -0.3 to $V_{CC} + 0.3$  | V    |
|                             | Port B                          |              | -0.3 to $AV_{CC} + 0.3$ | V    |
|                             | X1                              |              | -0.3 to 4.3             | V    |
| Operating temperature       | $T_{opr}$                       | -20 to +75   | °C                      |      |
| Storage temperature         | $T_{stg}$                       | -55 to +125  | °C                      |      |

Note: \* Permanent damage may result if maximum ratings are exceeded. Normal operation should be under the conditions specified in Electrical Characteristics. Exceeding these values can result in incorrect operation and reduced reliability.

## 23.2 Electrical Characteristics (F-ZTAT™ Version, EEPROM Stacked F-ZTAT™ Version)

### 23.2.1 Power Supply Voltage and Operating Ranges

#### Power Supply Voltage and Oscillation Frequency Range

## Power Supply Voltage and Operating Frequency Range

- AV<sub>CC</sub> = 3.3 to 5.5 V
- Active mode
- Sleep mode  
(When MA2 in SYSCR2 = 0 )

- AV<sub>CC</sub> = 3.3 to 5.5 V
- Subactive mode
- Subsleep mode

- AV<sub>CC</sub> = 3.3 to 5.5 V
- Active mode
- Sleep mode  
(When MA2 in SYSCR2 = 1 )

## Analog Power Supply Voltage and A/D Converter Accuracy Guarantee Range

### Range of Power Supply Voltage and Oscillation Frequency when Low-Voltage Detection Circuit is Used

## 23.2.2 DC Characteristics

**Table 23.2 DC Characteristics (1)**

$V_{CC} = 3.0$  to  $5.5$  V,  $V_{SS} = 0.0$  V,  $T_a = -20$  to  $+75^\circ\text{C}$ , unless otherwise indicated.

| Item               | Symbol   | Applicable Pins                                                                                                                                                | Test Condition             | Values               |     |                     | Unit | Notes |

- Notes:
1. Set  $AV_{CC} = V_{CC}$  when the A/D converter is not used.
  2.  $AI_{STOP1}$  is the current in active and sleep modes while the A/D converter is idle.
  3.  $AI_{STOP2}$  is the current at reset and in standby, subactive, and subsleep modes while the A/D converter is idle.

### 23.2.5 Watchdog Timer Characteristics

**Table 23.7 Watchdog Timer Characteristics**

$V_{CC} = 3.0$  to  $5.5$  V,  $V_{SS} = 0.0$  V,  $T_a = -20$  to  $+75^\circ\text{C}$ , unless otherwise indicated.

| Item                             | Symbol    | Applicable Pins | Test Condition | Values |     |     | Unit | Reference Figure |
|----------------------------------|-----------|-----------------|----------------|--------|-----|-----|------|------------------|
|                                  |           |                 |                | Min    | Typ | Max |      |                  |
| On-chip oscillator overflow time | $t_{OVF}$ |                 |                | 0.2    | 0.4 | —   | s    | *                |

Note: \* Shows the time to count from 0 to 255, at which point an internal reset is generated, when the internal oscillator is selected.

## 23.2.6 Flash Memory Characteristics

**Table 23.8 Flash Memory Characteristics**

$V_{CC} = 3.0$  to  $5.5$  V,  $V_{SS} = 0.0$  V,  $T_a = -20$  to  $+75^\circ\text{C}$ , unless otherwise indicated.

| Item                                                                          |                                                                | Symbol           | Test Condition         | Values |       |      | Unit  |

|         | Wait time after EV bit clear* <sup>1</sup> η                     |                | 4      | —   | —   | μs    |
|         | Wait time after SWE bit clear* <sup>1</sup>                      | θ              | 100    | —   | —   | μs    |
|         | Maximum erase count * <sup>1</sup> * <sup>6</sup> * <sup>7</sup> | N              | —      | —   | 120 | Times |

- Notes:
1. Make the time settings in accordance with the program/erase algorithms.
  2. The programming time for 128 bytes. (Indicates the total time for which the P bit in flash memory control register 1 (FLMCR1) is set. The program-verify time is not included.)
  3. The time required to erase one block. (Indicates the time for which the E bit in flash memory control register 1 (FLMCR1) is set. The erase-verify time is not included.)
  4. Programming time maximum value ( $t_p(\text{max.})$ ) = wait time after P bit setting (z) × maximum programming count (N)
  5. Set the maximum programming count (N) according to the actual set values of z1, z2, and z3, so that it does not exceed the programming time maximum value ( $t_p(\text{max.})$ ). The wait time after P bit setting (z1, z2) should be changed as follows according to the value of the programming count (n).  
Programming count (n)  
 $1 \leq n \leq 6$       z1 = 30 μs  
 $7 \leq n \leq 1000$       z2 = 200 μs
  6. Erase time maximum value ( $t_e(\text{max.})$ ) = wait time after E bit setting (z) × maximum erase count (N)
  7. Set the maximum erase count (N) according to the actual set value of (z), so that it does not exceed the erase time maximum value ( $t_e(\text{max.})$ ).

## 23.2.7 EEPROM Characteristics

**Table 23.9 EEPROM Characteristics**

$V_{CC} = 3.0\text{ V to }5.5\text{ V}$ ,  $V_{SS} = 0.0\text{ V}$ ,  $T_a = -20^{\circ}\text{C to }+75^{\circ}\text{C}$ , unless otherwise specified.

| Item                                        | Symbol     | Test Condition | Values |     |     | Unit          | Reference Figure |

| SDA input rise time                         | $t_{Sr}$   |                | —      | —   | 300 | ns            |                  |
| Data output hold time                       | $t_{DH}$   |                | 50     | —   | —   | ns            |                  |
| SCL, SDA capacitive load                    | $C_b$      |                | 0      | —   | 400 | pF            |                  |
| Access time                                 | $t_{AA}$   |                | 100    | —   | 900 | ns            |                  |
| Cycle time at writing*                      | $t_{WC}$   |                | —      | —   | 10  | ms            |                  |
| Reset release time                          | $t_{RES}$  |                | —      | —   | 13  | ms            |                  |

Note: \* Cycle time at writing is a time from the stop condition to write completion (internal control).

## 23.2.8 Power-Supply-Voltage Detection Circuit Characteristics (Optional)

**Table 23.10 Power-Supply-Voltage Detection Circuit Characteristics**

$V_{SS} = 0.0 \text{ V}$ ,  $T_a = -20 \text{ to } +75^\circ\text{C}$ , unless otherwise indicated.

| Item                                                | Symbol        | Test Condition                                                           | Values |     |     | Unit          |
|-----------------------------------------------------|---------------|--------------------------------------------------------------------------|--------|-----|-----|---------------|
|                                                     |               |                                                                          | Min    | Typ | Max |               |
| Power-supply falling detection voltage              | Vint (D)      | LVDSEL = 0                                                               | 3.3    | 3.7 | —   | V             |
| Power-supply rising detection voltage               | Vint (U)      | LVDSEL = 0                                                               | —      | 4.0 | 4.5 | V             |
| Reset detection voltage 1* <sup>1</sup>             | Vreset1       | LVDSEL = 0                                                               | —      | 2.3 | 2.7 | V             |
| Reset detection voltage 2* <sup>2</sup>             | Vreset2       | LVDSEL = 1                                                               | 3.0    | 3.6 | 4.2 | V             |
| Lower-limit voltage of LVDR operation* <sup>3</sup> | $V_{LVDRmin}$ |                                                                          | 1.0    | —   | —   | V             |
| LVD stabilization time                              | $t_{LVDON}$   |                                                                          | 50     | —   | —   | $\mu\text{s}$ |
| Current consumption in standby mode                 | $I_{STBY}$    | LVDE = 1,<br>Vcc = 5.0 V,<br>When a 32-kHz crystal resonator is not used | —      | —   | 350 | $\mu\text{A}$ |

- Notes: 1. This voltage should be used when the falling and rising voltage detection function is used.
2. Select the low-voltage reset 2 when only the low-voltage detection reset is used.
3. When the power-supply voltage (Vcc) falls below  $V_{LVDRmin} = 1.0 \text{ V}$  and then rises, a reset may not occur. Therefore sufficient evaluation is required.

## 23.2.9 Power-On Reset Circuit Characteristics (Optional)

**Table 23.11 Power-On Reset Circuit Characteristics**

$V_{SS} = 0.0 \text{ V}$ ,  $T_a = -20 \text{ to } +75^\circ\text{C}$ , unless otherwise indicated.

| Item                          | Symbol    | Test Condition | Values |     |     | Unit             |
|-------------------------------|-----------|----------------|--------|-----|-----|------------------|
|                               |           |                | Min    | Typ | Max |                  |
| Pull-up resistance of RES pin | $R_{RES}$ |                | 100    | 150 | —   | $\text{k}\Omega$ |
| Power-on reset start voltage* | $V_{por}$ |                | —      | —   | 100 | mV               |

Note: \* The power-supply voltage (Vcc) must fall below  $V_{por} = 100 \text{ mV}$  and then rise after charge of the RES pin is removed completely. In order to remove charge of the RES pin, it is recommended that the diode be placed in the Vcc side. If the power-supply voltage (Vcc) rises from the point over 100 mV, a power-on reset may not occur.

## 23.3 Electrical Characteristics (Mask-ROM Version, EEPROM Stacked Mask-ROM Version)

### 23.3.1 Power Supply Voltage and Operating Ranges

#### Power Supply Voltage and Oscillation Frequency Range

#### Power Supply Voltage and Operating Frequency Range

## Analog Power Supply Voltage and A/D Converter Accuracy Guarantee Range

- $V_{CC} = 2.7$  to 5.5 V
- Active mode
- Sleep mode

### Range of Power Supply Voltage and Oscillation Frequency when Low-Voltage Detection Circuit is Used

- Operation guarantee range
- Operation guarantee range except A/D conversion accuracy

## 23.3.2 DC Characteristics

**Table 23.12 DC Characteristics (1)**

$V_{CC} = 2.7$  to  $5.5$  V,  $V_{SS} = 0.0$  V,  $T_a = -20$  to  $+75^\circ\text{C}$ , unless otherwise indicated.

Notes: 1. Set  $AV_{CC} = V_{CC}$  when the A/D converter is not used.  
2.  $AI_{STOP1}$  is the current in active and sleep modes while the A/D converter is idle.  
3.  $AI_{STOP2}$  is the current at reset and in standby, subactive, and subsleep modes while the A/D converter is idle.

### 23.3.5 Watchdog Timer Characteristics

**Table 23.17 Watchdog Timer Characteristics**

$V_{CC} = 2.7$  to  $5.5$  V,  $V_{SS} = 0.0$  V,  $T_a = -20$  to  $+75^\circ\text{C}$ , unless otherwise indicated.

| Item                             | Symbol    | Applicable Pins | Test Condition | Values |     |     | Unit | Reference Figure |
|----------------------------------|-----------|-----------------|----------------|--------|-----|-----|------|------------------|
|                                  |           |                 |                | Min    | Typ | Max |      |                  |
| On-chip oscillator overflow time | $t_{OVF}$ |                 |                | 0.2    | 0.4 | —   | s    | *                |

Note: \* Shows the time to count from 0 to 255, at which point an internal reset is generated, when the internal oscillator is selected.

### 23.3.6 EEPROM Characteristics

**Table 23.18 EEPROM Characteristics**

$V_{CC} = 2.7\text{ V to }5.5\text{ V}$ ,  $V_{SS} = 0.0\text{ V}$ ,  $T_a = -20^{\circ}\text{C to }+75^{\circ}\text{C}$ , unless otherwise indicated.

| Item                                        | Symbol     | Test Condition | Values |     |     | Unit          | Reference Figure |

| Power-supply rising detection voltage               | Vint (U)      | LVDSEL = 0                                                               | —      | 4.0 | 4.5 | V             |
| Reset detection voltage 1* <sup>1</sup>             | Vreset1       | LVDSEL = 0                                                               | —      | 2.3 | 2.7 | V             |
| Reset detection voltage 2* <sup>2</sup>             | Vreset2       | LVDSEL = 1                                                               | 3.0    | 3.6 | 4.2 | V             |
| Lower-limit voltage of LVDR operation* <sup>3</sup> | $V_{LVDRmin}$ |                                                                          | 1.0    | —   | —   | V             |
| LVD stabilization time                              | $t_{LVDRON}$  |                                                                          | 50     | —   | —   | $\mu\text{s}$ |
| Current consumption in standby mode                 | $I_{STBY}$    | LVDE = 1,<br>Vcc = 5.0 V,<br>When a 32-kHz crystal resonator is not used | —      | —   | 350 | $\mu\text{A}$ |

- Notes: 1. This voltage should be used when the falling and rising voltage detection function is used.
2. Select the low-voltage reset 2 when only the low-voltage detection reset is used.
3. When the power-supply voltage (Vcc) falls below  $V_{LVDRmin} = 1.0 \text{ V}$  and then rises, a reset may not occur. Therefore sufficient evaluation is required.

### 23.3.8 Power-On Reset Circuit Characteristics (Optional)

**Table 23.20 Power-On Reset Circuit Characteristics**

$V_{SS} = 0.0 \text{ V}$ ,  $T_a = -20 \text{ to } +75^\circ\text{C}$ , unless otherwise indicated.

| Item                          | Symbol    | Test Condition | Values |     |     | Unit       |
|-------------------------------|-----------|----------------|--------|-----|-----|------------|
|                               |           |                | Min    | Typ | Max |            |
| Pull-up resistance of RES pin | $R_{RES}$ |                | 100    | 150 | —   | k $\Omega$ |
| Power-on reset start voltage* | $V_{por}$ |                | —      | —   | 100 | mV         |

- Note: \* The power-supply voltage (Vcc) must fall below  $V_{por} = 100 \text{ mV}$  and then rise after charge of the RES pin is removed completely. In order to remove charge of the RES pin, it is recommended that the diode be placed in the Vcc side. If the power-supply voltage (Vcc) rises from the point over 100 mV, a power-on reset may not occur.

### Condition Code

| Symbol   | Description                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| Rd       | General destination register                                                                                                          |
| Rs       | General source register                                                                                                               |
| Rn       | General register                                                                                                                      |
| ERd      | General destination register (address register or 32-bit register)                                                                    |
| ERs      | General source register (address register or 32-bit register)                                                                         |
| ERn      | General register (32-bit register)                                                                                                    |
| (EAd)    | Destination operand                                                                                                                   |
| (EAs)    | Source operand                                                                                                                        |
| PC       | Program counter                                                                                                                       |
| SP       | Stack pointer                                                                                                                         |
| CCR      | Condition-code register                                                                                                               |
| N        | N (negative) flag in CCR                                                                                                              |
| Z        | Z (zero) flag in CCR                                                                                                                  |
| V        | V (overflow) flag in CCR                                                                                                              |
| C        | C (carry) flag in CCR                                                                                                                 |
| disp     | Displacement                                                                                                                          |
| →        | Transfer from the operand on the left to the operand on the right, or transition from the state on the left to the state on the right |
| +        | Addition of the operands on both sides                                                                                                |
| −        | Subtraction of the operand on the right from the operand on the left                                                                  |
| ×        | Multiplication of the operands on both sides                                                                                          |
| ÷        | Division of the operand on the left by the operand on the right                                                                       |
| ^        | Logical AND of the operands on both sides                                                                                             |
| ∨        | Logical OR of the operands on both sides                                                                                              |
| ⊕        | Logical exclusive OR of the operands on both sides                                                                                    |
| ¬        | NOT (logical complement)                                                                                                              |
| ( ), < > | Contents of operand                                                                                                                   |

Note: General registers include 8-bit registers (R0H to R7H and R0L to R7L) and 16-bit registers (R0 to R7 and E0 to E7).

## Condition Code Notation (cont)

| Symbol | Description                                        |
|--------|----------------------------------------------------|
| ↕      | Changed according to execution result              |
| *      | Undetermined (no guaranteed value)                 |
| 0      | Cleared to 0                                       |
| 1      | Set to 1                                           |
| —      | Not affected by execution of the instruction       |
| Δ      | Varies depending on conditions, described in notes |

- Notes: 1. The number of states in cases where the instruction code and its operands are located in on-chip memory is shown here. For other cases see section A.3, Number of Execution States.
2. n is the value set in register R4L or R4.
- (1) Set to 1 when a carry or borrow occurs at bit 11; otherwise cleared to 0.
  - (2) Set to 1 when a carry or borrow occurs at bit 27; otherwise cleared to 0.
  - (3) Retains its previous value when the result is zero; otherwise cleared to 0.
  - (4) Set to 1 when the adjustment produces a carry; otherwise retains its previous value.
  - (5) The number of states required for execution of an instruction that transfers data in synchronization with the E clock is variable.
  - (6) Set to 1 when the divisor is negative; otherwise cleared to 0.
  - (7) Set to 1 when the divisor is zero; otherwise cleared to 0.
  - (8) Set to 1 when the quotient is negative; otherwise cleared to 0.

## A.2 Operation Code Map

Table A.2 Operation Code Map (1)

| 1st byte |    | 2nd byte |    |
|----------|----|----------|----|

Notes: 1. r is the register designation field.  
 2. aa is the absolute address field.

### A.3 Number of Execution States

The status of execution for each instruction of the H8/300H CPU and the method of calculating the number of states required for instruction execution are shown below. Table A.4 shows the number of cycles of each type occurring in each instruction, such as instruction fetch and data read/write. Table A.3 shows the number of states required for each cycle. The total number of states required for execution of an instruction can be calculated by the following expression:

$$\text{Execution states} = I \times S_I + J \times S_J + K \times S_K + L \times S_L + M \times S_M + N \times S_N$$

**Examples:** When instruction is fetched from on-chip ROM, and an on-chip RAM is accessed.

BSET #0, @FF00

From table A.4:

$$I = L = 2, \quad J = K = M = N = 0$$

From table A.3:

$$S_I = 2, \quad S_L = 2$$

$$\text{Number of states required for execution} = 2 \times 2 + 2 \times 2 = 8$$

When instruction is fetched from on-chip ROM, branch address is read from on-chip ROM, and on-chip RAM is used for stack area.

JSR @@ 30

From table A.4:

$$I = 2, \quad J = K = 1, \quad L = M = N = 0$$

From table A.3:

$$S_I = S_J = S_K = 2$$

$$\text{Number of states required for execution} = 2 \times 2 + 1 \times 2 + 1 \times 2 = 8$$

**Table A.3 Number of Cycles in Each Instruction**

| Execution Status<br>(Instruction Cycle) |       | Access Location |                           |
|-----------------------------------------|-------|-----------------|---------------------------|
|                                         |       | On-Chip Memory  | On-Chip Peripheral Module |
| Instruction fetch                       | $S_I$ | 2               | —                         |
| Branch address read                     | $S_J$ |                 |                           |
| Stack operation                         | $S_K$ |                 |                           |
| Byte data access                        | $S_L$ |                 | 2 or 3*                   |
| Word data access                        | $S_M$ |                 | 2 or 3*                   |
| Internal operation                      | $S_N$ |                 | 1                         |

Note: \* Depends on which on-chip peripheral module is accessed. See section 22.1, Register Addresses (Address Order).

**Table A.4 Number of Cycles in Each Instruction**

| Instruction | Mnemonic          | Instruction | Branch     | Stack     | Byte Data | Word Data | Internal  |
|-------------|-------------------|-------------|------------|-----------|-----------|-----------|-----------|
|             |                   | Fetch       | Addr. Read | Operation | Access    | Access    | Operation |

## B.2 Port States in Each Operating State

| Port                      | Reset          | Sleep          | Subsleep       | Standby                      | Subactive      | Active         |
|---------------------------|----------------|----------------|----------------|------------------------------|----------------|----------------|
| P17 to P14,<br>P12 to P10 | High impedance | Retained       | Retained       | High impedance* <sup>1</sup> | Functioning    | Functioning    |
| P24 to P20                | High impedance | Retained       | Retained       | High impedance               | Functioning    | Functioning    |
| P37 to P30                | High impedance | Retained       | Retained       | High impedance               | Functioning    | Functioning    |
| P57 to P50* <sup>2</sup>  | High impedance | Retained       | Retained       | High impedance* <sup>1</sup> | Functioning    | Functioning    |
| P67 to P60                | High impedance | Retained       | Retained       | High impedance               | Functioning    | Functioning    |
| P76 to P74,<br>P72 to P70 | High impedance | Retained       | Retained       | High impedance               | Functioning    | Functioning    |
| P87 to P85                | High impedance | Retained       | Retained       | High impedance               | Functioning    | Functioning    |
| PB7 to PB0                | High impedance | High impedance | High impedance | High impedance               | High impedance | High impedance |

Notes: 1. High level output when the pull-up MOS is in on state.

2. The P55 to P50 pins are applied to the H8/3687N.

# Appendix C Product Code Lineup

| Product Classification |                      |                         | Product Code | Model Marking     | Package Code     |
|------------------------|----------------------|-------------------------|--------------|-------------------|------------------|
| H8/3687                | Flash memory version | Standard product        | HD64F3687H   | HD64F3687H        | QFP-64 (FP-64A)  |
|                        |                      |                         | HD64F3687FP  | HD64F3687FP       | LQFP-64 (FP-64E) |
|                        |                      | Product with POR & LVDC | HD64F3687GH  | HD64F3687GH       | QFP-64 (FP-64A)  |
|                        |                      |                         | HD64F3687GFP | HD64F3687GFP      | LQFP-64 (FP-64E) |
|                        | Mask ROM version     | Standard product        | HD6433687H   | HD6433687(***)H   | QFP-64 (FP-64A)  |
|                        |                      |                         | HD6433687FP  | HD6433687(***)FP  | LQFP-64 (FP-64E) |

### Legend

(\*\*\*) : ROM code.

POR & LVDC: Power-on reset and low-voltage detection circuits.

# Appendix D Package Dimensions

The package dimensions that are shown in the Renesas Semiconductor Packages Data Book have priority.

**Figure D.1 FP-64E Package Dimensions**

Unit: mm

|                        |          |
|------------------------|----------|
| Package Code           | FP-64A   |
| JEDEC                  | —        |
| EIAJ                   | Conforms |
| Mass (reference value) | 1.2 g    |

\*Dimension including the plating thickness  
Base material dimension

| Figure 13.32 (2) Example of Complementary PWM Mode Operation (TPSC2 = TPSC1 = TPSC0 ≠ 0) (3) | 215  | Added                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                                              | 216  | When the counter is incremented or decremented, the IMFA flag of channel 0 is set to 1, and when the register is underflowed, the UDF flag of channel 0 is set to 1. After buffer operation has been designated for BR, BR is transferred to GR when the counter is incremented by compare match A0 or when TCNT_1 is underflowed. If the $\phi$ or $\phi/2$ clock is selected by bits TPSC2 to TPSC0, the OVF flag is not set to 1 at the timing that the counter value changes from H'FFFF to H'0000. If the $\phi/4$ or $\phi/8$ clock is selected by bits TPSC2 to TPSC0, the OVF flag is set to 1. |
| 3. Setting GR Value in Complementary PWM Mode                                                | 217  | <p>A. Initial value</p> <ol style="list-style-type: none"> <li>When other than TPSC2 = TPSC1 = TPSC0 = 0, the GRA_0 value must be equal to H'FFFC or less. When TPSC2 = TPSC1 = TPSC0 = 0, the GRA_0 value can be set to H'FFFF or less.</li> <li>H'0000 to T - 1 (T: Initial value of TCNT0) must not be set for the initial value.</li> <li>GRA_0 - (T - 1) or more must not be set for the initial value.</li> <li>When using buffer operation, the same values must be set in the buffer registers and corresponding general registers.</li> </ol>                                                  |
| Descriptions of B. Modifying the setting value are Modified                                  |      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Figure 17.20 Sample Flowchart for Slave Receive Mode                    | 318             | Supplementary explanation: When one byte is received, steps [2] to [6] are skipped after step [1], before jumping to step [7]. The step [8] is dummy-read in ICDRR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                      |                 |                      |          |         |        |        |      |     |     |                    |            |                                             |                      |   |                 |   |                                             |                      |   |                 |                   |            |                                             |             |             |                      |     |                                             |             |   |                      |   |        |             |   |   |   |      |             |             |             |             |      |             |   |   |   |
