27C512

512K (64K x 8) CMOS EPROM

FEATURES

- High speed performance
  - —90ns access time available
- CMOS Technology for low power consumption
  - —35mA Active current
  - —100μA Standby current
- Factory programming available
- Auto-insertion-compatible plastic packages
- Auto ID™ aids automated programming
- High speed express programming algorithm
- Organized 64K x 8: JEDEC standard pinouts
  - —28-pin Dual-in-line package
  - —32-pin Chip carrier (leadless or plastic)
  - —28-pin SOIC package
  - —28-pin TSOP
  - —Tape and reel
- Available for the following temperature ranges:
  - —Commercial: 0° C to 70° C
  - —Industrial: -40° C to 85° C
  - —Automotive: -40° C to 125° C

DESCRIPTION

The Microchip Technology Inc. 27C512 is a CMOS 512K bit (electrically) Programmable Read Only Memory. The device is organized into 64K words by 8 bits (64K bytes). Accessing individual bytes from an address transition or from power-up (chip enable pin going low) is accomplished in less than 90ns. This very high speed device allows the most sophisticated microprocessors to run at full speed without the need for WAIT states. CMOS design and processing enables this part to be used in systems where reduced power consumption and high reliability are requirements.

A complete family of packages is offered to provide the most flexability in applications. For surface mount applications, PLCC or SOIC packaging is available. Tape or reel packaging is also available for PLCC or SOIC packages. UV erasable versions are also available.

Read Mode

(See Timing Diagrams and AC Characteristics)

Read Mode is accessed when

a) the $\overline{CE}$ pin is low to power up (enable) the chip

b) the $\overline{OE}/V_{PP}$ pin is low to gate the data to the output pins.

For Read operations, if the addresses are stable, the address access time (t_{ACC}) is equal to the delay from $\overline{CE}$ to output (t_{CE}). Data is transferred to the output after a delay (t_{OE}) from the falling edge of $\overline{OE}/V_{PP}$.

Standby Mode

The standby mode is defined when the $\overline{CE}$ pin is high and a program mode is not identified.

When this condition is met, the supply current will drop from 35mA to 100μA.

Output Enable $\overline{OE}$/VPP

This multifunction pin eliminates bus connection in multiple bus microprcessor systems and the outputs go to high impedance when:

• the $\overline{OE}$/VPP pin is high (VIH).

When a VH input is applied to this pin, it supplies the programming voltage (VPP) to the device.

Erase Mode (UV Windowed Versions)

Windowed products offer the ability to erase the memory array. The memory matrix is erased to the all "1's" state as a result of being exposed to ultraviolet light. To ensure complete erasure, a dose of 15 watt-second/cm^2 is required. This means that the device window must be placed within one inch and directly underneath an ultraviolet lamp with a wavelength of 2537 Angstroms, intensity of 12,000μW/cm^2 for approximately 20 minutes.

Programming Mode

The Express algorithm has been developed to improve on the programming throughput times in a production environment. Up to 10 100-microsecond pulses are applied until the byte is verified. A flowchart of the Express algorithm is shown in Figure 1.

Programming takes place when:

a) VCC is brought to the proper voltage,
b) $\overline{OE}$/VPP is brought to the proper VH level, and
c) $\overline{CE}$ line is low.

Since the erased state is "1" in the array, programming of "0" is required. The address to be programmed is set via pins A0 - A15 and the data to be programmed is presented to pins O0 - O7. When data and address are stable, a low going pulse on the $\overline{CE}$ line programs that location.

Verify

After the array has been programmed it must be verified to ensure all the bits have been correctly programmed. This mode is entered when all the following conditions are met:

a) VCC is at the proper level,
b) the $\overline{OE}$/VPP pin is low, and
c) the $\overline{CE}$ line is low.

Inhibit

When programming multiple devices in parallel with different data, only $\overline{CE}$ needs to be under separate control to each device. By pulsing the $\overline{CE}$ line low on a particular device, that device will be programmed; all other devices with $\overline{CE}$ held high will not be programmed with the data (although address and data will be available on their input pins).

Identity Mode

In this mode specific data is output which identifies the manufacturer as Microchip Technology Inc and the device type. This mode is entered when Pin A9 is taken to VH (11.5V to 12.5V). The $\overline{CE}$ and $\overline{OE}$/VPP lines must be at VIL. A0 is used to access any of the two non-erasable bytes whose data appears on O0 through O7.
