CY7C107

1M x 1 Static R/W RAM

Features

- High speed
— $t_{AA} = 25$ ns
- CMOS for optimum speed/power
- Low active power
— 825 mW
- Low standby power
— 165 mW
- Automatic power-down when deselected
- TTL-compatible inputs and outputs

Functional Description

The CY7C107 is a high-performance CMOS static RAM organized as 1,048,576 words by 1 bit. Easy memory expansion is provided by an active LOW chip enable (CE) and three-state drivers. The device has an automatic power-down feature that reduces power consumption by more than 70% when deselected.

Writing to the device is accomplished by taking chip enable (CE) and write enable (WE) inputs LOW. Data on the input pin (D_{IN}) is written into the memory location specified on the address pins (A_0 through A_{19}).

Reading from the device is accomplished by taking chip enable (CE) LOW while write enable (WE) remains HIGH. Under these conditions, the contents of the memory location specified by the address pins will appear on the data output (D_{OUT}) pin.

The output pin (D_{OUT}) is placed in a high-impedance state when the device is deselected (CE HIGH) or during a write operation (CE and WE LOW).

The CY7C107 is available in 32-pin leadless chip carriers and standard 28-pin, 400-mil-wide DIPs and SOJs.

Notes:

- V_{IL} (min.) = -2.0V for pulse durations of less than 20 ns.
- T_A is the "instant on" case temperature.
- See the last page of this specification for Group A subgroup testing information.
- Not more than 1 output should be shorted at one time. Duration of the short circuit should not exceed 30 seconds.
- Tested initially and after any design or process changes that may affect these parameters.

t _{HZWE}	WE LOW to High Z ^[7, 8]		15		20		25	ns

Notes:

- Test conditions assume signal transition time of 5 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
- At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE} and t_{HZWE} is less than t_{LZWE} for any given device.
- t_{HZCE} and t_{HZWE} are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads. Transition is measured ± 500 mV from steady state voltage.
- The internal write time of the memory is defined by the overlap of $\overline{CE}$ LOW and $\overline{WE}$ LOW. $\overline{CE}$ and $\overline{WE}$ must be LOW to initiate a write, and the transition of any of these signals can terminate the write. The input data set-up and hold timing should be referenced to the leading edge of the signal that terminates the write.

Notes:

10. Device is continuously selected, $\overline{CE} = V_{IL}$.11. $\overline{WE}$ is HIGH for read cycle.12. Address valid prior to or coincident with $\overline{CE}$ transition LOW.13. If $\overline{CE}$ goes HIGH simultaneously with $\overline{WE}$ going HIGH, the output remains in a high-impedance state.
