

MAXIM

CMOS Quad 8-Bit D/A Converters

General Description

Maxim's MX7225 and MX7226 each contain four 8-bit voltage-output digital-to-analog converters (DACs). They include output buffer amplifiers and input logic for simple microprocessor and TTL/CMOS interfaces. 8-bit performance is achieved over the full operating temperature range without external trimming.

The MX7225 contains double-buffered logic inputs that allow all analog outputs to be simultaneously updated using one control signal. There are also four separate reference inputs so that the range of each DAC can be independently set.

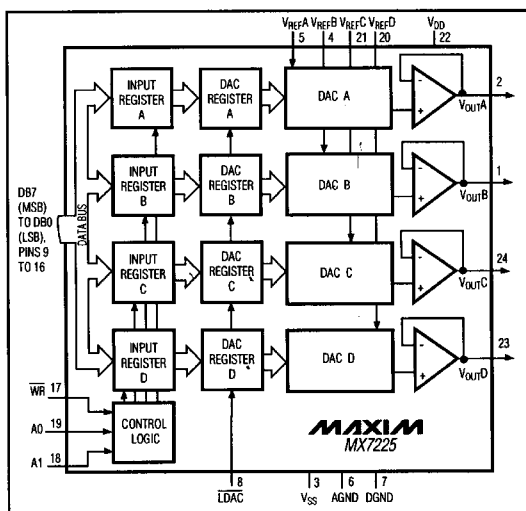

The MX7226 has separate input registers for each of its four DACs. Data is transferred into an input register from a common 8-bit TTL/CMOS-compatible input port. Address inputs A0 and A1 determine which DAC is loaded when WR goes low. All DACs share a common reference input.

For '7225 and '7226 designs utilizing a 5V supply, see the MAX505 and MAX506 data sheet.

Applications

Minimum Component Count Analog Systems
Digital Offset/Gain Adjustment
Industrial Process Control
Arbitrary Function Generators
Automatic Test Equipment
Microprocessor-Controlled Calibration

Functional Block Diagram

Features

- ◆ Buffered Voltage Output
- ◆ Double-Buffered Inputs (MX7225)
- ◆ Microprocessor and TTL/CMOS Compatible
- ◆ Operate from Single or Dual Supplies
- ◆ Require No External Adjustments

Typical Operating Characteristics

CMOS Quad 8-Bit D/A Converters

MX7225/MX7226

Detailed Description

The MX7225 and MX7226 have four matched voltage output digital-to-analog converters (DACs). The DAC's are "inverted" R-2R ladder networks which convert 8 bit digital words into equivalent analog output voltages in proportion to the applied reference voltage(s). Each DAC in the MX7225 has a separate reference input whereas in the MX7226, all reference inputs are tied together. A simplified circuit diagram of one of the four DACs is provided in Figure 1.

V_{REF} Input

The voltage at V_{REF} sets the full-scale output of the DAC. The input impedance of the V_{REF} input(s) is code dependent. The lowest value, approximately 11k Ω for the MX7225 and 2k Ω for the MX7226, occurs when the input code is 01010101. The maximum value is infinity, which occurs when the input code is 00000000. Because the input resistance at V_{REF} is code dependent, the DAC's reference sources must have an output impedance of no more than 20 Ω for the MX7225 and 4 Ω for the MX7226, to maintain output linearity. The input

capacitance at V_{REF} is also code dependent and typically varies from 15pF to 35pF for the MX7225 and 100pF to 250pF for the MX7226.

$V_{OUT} A$, B , C , or D can be represented by a digitally programmable voltage source as:

$$V_{OUT} = N_B \times V_{REF}/256,$$

where N_B is the numeric value of the DAC's binary input code.

Output Buffer Amplifiers

All MX7225/26 voltage outputs are internally buffered by precision unity gain followers which slew at greater than 3V/ μ s. When driving 2k Ω in parallel with 100pF with full scale transitions (0V to +10V or +10V to 0V), the output settles to $\pm 1/2$ LSB in less than 4 μ s. Typical dynamic response and settling performance of the MX7225 and MX7226 is shown in Figure 2 and 3.

A simplified circuit diagram of an output buffer is shown in Figure 4. Input common mode range to AGND is provided by a PMOS input structure. The improved

Figure 1. Simplified DAC Circuit Diagram

CMOS Quad 8-Bit D/A Converters

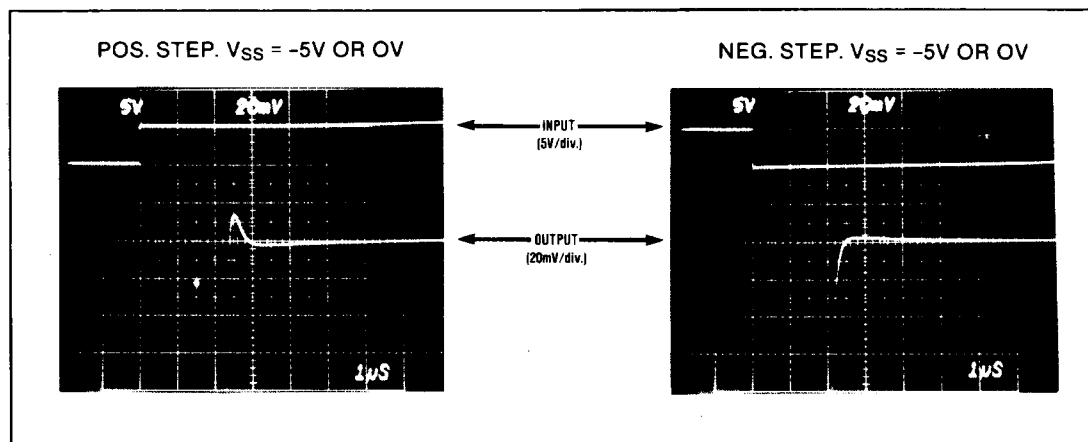

Figure 2. Positive and Negative Settling Times, $V_{SS} = 0V$ or $-5V$

Figure 3. Dynamic Response, $V_{SS} = 0V$ or $-5V$

output circuitry incorporates a Maxim proprietary pull-down circuit to actively drive V_{OUT} to within typically $+15mV$ of the negative supply (V_{SS}). The buffer circuitry allows each DAC output to sink, as well as source, up to $5mA$. This is especially important in single supply applications, where V_{SS} is connected to GND, so that zero error is kept at or under $1/2LSB$ ($V_{REF} = +10V$). A plot of output sink current versus output voltage is shown in the Typical Operating Characteristics section.

Digital Inputs and Interface Logic

The digital inputs are compatible with both TTL and 5V CMOS logic, however power supply currents, I_{DD} and I_{SS} , are somewhat dependent on input logic level. Supply currents are specified for TTL input levels (worst case) but are significantly reduced when the logic inputs are driven as close to DGND as possible, or above 4 volts.

Figure 4. Simplified Output Buffer Circuit

Address lines A0 and A1 select which DAC receives data from the input port. When WR is low, the input register of the addressed DAC is transparent. The data is then latched when WR goes high. Figure 5 shows the input control logic for the MX7225 and MX7226. Table 1 lists the channel addresses.

The MX7226's four DAC outputs represent the data held in four 8 bit input registers. The MX7225 differs from the MX7226 in that in addition to the input registers, there is a separate DAC register for each DAC as well. A DAC's analog output is based only on the contents of its DAC register. Data is transferred from the input registers to the DAC registers by the $LDAC$ input. When $LDAC$ is LOW, all four DAC registers are transparent to the input registers so that all DACs are updated simultaneously. With $LDAC$ held LOW, the MX7225 interface behaves like the MX7226.

Since $LDAC$ (MX7225 only) is asynchronous with respect to WR , care must be taken to assure that incorrect data is not latched through to the output. If $LDAC$ is brought LOW before or at the same time that WR goes HIGH, then $LDAC$ must remain LOW for at least t_{LD} to ensure that the correct data is latched. Data is latched into all four DAC registers on the

rising edge of LDAC. Table 2 shows the truth table for WR and LDAC operation. Figure 6 shows the write cycle timing for both the MX7225 and MX7226.

Applications Information

Power Supply and Reference Operating Ranges

The MX7225 and MX7226 are fully specified to operate with V_{DD} between $+12V \pm 5\%$ and $+15V \pm 10\%$ ($+11.4V$ to $+16.5V$), and with V_{SS} from $0V$ to $-5.5V$. 8 bit performance is also guaranteed for single supply operation ($V_{SS} = 0V$), however zero code error is reduced when V_{SS} is $-5V$ (see Output Buffer Amplifier).

For adequate DAC and buffer operating range, the V_{REF} voltage must always be at least $4V$ below V_{DD} . Both the MX7225 and MX7226 are specified to operate with a reference input range of $+2V$ to $V_{DD} - 4V$.

Ground Management

Digital or AC transient signals between AGND and DGND will create noise at the analog outputs. It is recommended that AGND and DGND be tied together at the DAC and that this point be tied to the highest quality ground that is available. If separate ground busses are used, then two clamp diodes (1N914 or equivalent) should be connected between AGND and DGND to keep the two ground busses within one diode drop of each other. To avoid parasitic device turn-on, AGND must not be allowed to be more negative than DGND. DGND should be used as supply ground for bypassing purposes.

Careful PCB ground layout techniques should be used to minimize crosstalk between DAC outputs, the reference input(s), and the digital inputs. This is particularly important if the reference is driven from an AC source. Figure 7 and 8 show suggested circuit board layouts for minimizing crosstalk.

Unipolar Output

In unipolar operation, the output voltages and the reference input(s) are the same polarity. Unipolar circuit configurations are shown in Figure 9 and 10 for the MX7225 and MX7226. Both devices can be operated from a single supply with a slight increase in zero error (see Output Buffer Amplifier section). To avoid parasitic device turn-on, the voltage at V_{REF} must always be positive with respect to DGND. The unipolar code table is given in Table 3.

Bipolar Output

Each DAC output may be configured for bipolar operation using the circuit in Figure 11. One op-amp and two resistors are required per channel. With $R1 = R2$:

$$V_{OUT} = V_{REF}(2D_A - 1),$$

where D_A is a fractional representation of the digital word in register A.

Table 4 shows the digital code versus output voltage for the circuit in Figure 11.

CMOS Quad 8-Bit D/A Converters

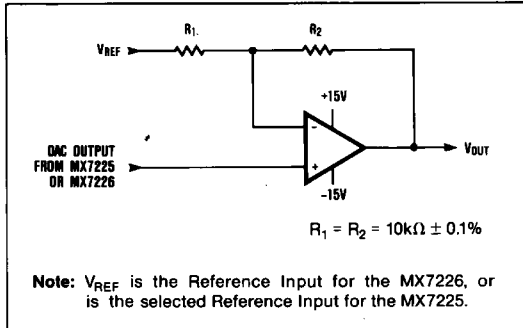

Figure 11. Bipolar Output Circuit

Offsetting AGND

AGND can be biased above DGND to provide an arbitrary nonzero output voltage for a "zero" input code. This is shown in Figure 12. The output voltage at V_{OUTA} is:

$$V_{OUTA} = V_{BIAS} + D_A V_{IN}$$

where D_A is a fractional representation of the digital input word. Since AGND is common to all four DAC's, all outputs will be offset by V_{BIAS} in the same manner.

Using an AC Reference

In applications where V_{REF} has AC signal components, the MX7225 and MX7226 have multiplying capability within the limits of the V_{REF} input range specifications. Figure 13 shows a technique for applying a sine wave signal to the reference input where the AC signal is biased up before being applied to V_{REF} . Output distortion is typically less than 0.1% with input frequencies up to 50kHz, and the typical -3dB frequency is 700kHz. Note that V_{REF} must never be more negative than AGND.

Generating V_{SS}

The performance of the MX7225/7226 is specified for both dual and single supply ($V_{SS} = 0V$) operation. When the improved performance of dual supply operation is desired, but only a single supply is available, a -5V V_{SS} supply can be generated using an ICL7660 in one of the circuits of figure 14.
