## REVISION HISTORY

Revision 0: Initial Version

## SPECIFICATIONS

$T_A = T_{MIN}$  to  $T_{MAX}$ ,  $V_{CC} = V_{MIN}$  to  $V_{MAX}$ , unless otherwise noted.

All voltages are measured with respect to GND, unless otherwise specified. Typicals are at  $T_A = 25^\circ\text{C}$  and represent most likely parametric norm. Logic inputs accept input high voltages up to  $V_{MAX}$  even when device is operating down to  $V_{MIN}$ . Timing specifications are tested at logic levels of  $V_{IL} = 0.8\text{ V}$  for a falling edge and  $V_{IH} = 2.0\text{ V}$  for a rising edge. SMBus timing specifications are guaranteed by design and are not production tested.

**Table 1.**

| Parameter                                                          | Min    | Typ       | Max       | Unit             | Test Conditions/Comments                                                                                  |

## ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter                                   | Rating           |
|---------------------------------------------|------------------|
| Positive Supply Voltage ( $V_{CC}$ )        | 5.5 V            |
| Maximum Voltage on 12 $V_{IN}$ Pin          | 20 V             |
| Voltage on Any Input or Output Pin          | −0.3 V to +6.5 V |
| Input Current at Any Pin                    | ±5 mA            |
| Package Input Current                       | ±20 mA           |
| Maximum Junction Temperature ( $T_{JMAX}$ ) | 150°C            |
| Storage Temperature Range                   | −65°C to +150°C  |
| Lead Temperature, Soldering                 |                  |
| IR Reflow Peak Temperature                  | 220°C            |
| Lead Temperature (Soldering 10 s)           | 300°C            |
| ESD Rating                                  | 1000 V           |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### THERMAL CHARACTERISTICS

24-lead QSOP package:

$$\theta_{JA} = 150^{\circ}\text{C/W}$$

$$\theta_{JC} = 39^{\circ}\text{C/W}$$

### ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 3. Pin Configuration

Table 3. Pin Function Descriptions

| Pin No. | Mnemonic                     | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | SDA                          | Digital I/O (Open Drain). SMBus bidirectional serial data. Requires pull-up resistor.                                                                                                                                                                                                                                                                                                                          |
| 2       | SCL                          | Digital Input (Open Drain). SMBus serial clock input. Requires pull-up resistor.                                                                                                                                                                                                                                                                                                                               |
| 3       | GND                          | Ground Pin.                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4       | V <sub>CC</sub>              | Power Supply. Can be powered by 3.3 V standby, if monitoring in low power states is required. V <sub>CC</sub> is also monitored through this pin. The ADT7468 can also be powered from a 5 V supply. Setting Bit 7 of Configuration Register 1 (Reg. 0x40) rescales the V <sub>CC</sub> input attenuators to correctly measure a 5 V supply.                                                                   |
| 5       | VID0                         | Digital Input (Open Drain). Voltage supply readouts from CPU. This value is read into the VID register (Reg. 0x43).                                                                                                                                                                                                                                                                                            |
| 6       | VID1                         | Digital Input (Open Drain). Voltage supply readouts from CPU. This value is read into the VID register (Reg. 0x43).                                                                                                                                                                                                                                                                                            |
| 7       | VID2                         | Digital Input (Open Drain). Voltage supply readouts from CPU. This value is read into the VID register (Reg. 0x43).                                                                                                                                                                                                                                                                                            |
| 8       | VID3                         | Digital Input (Open Drain). Voltage supply readouts from CPU. This value is read into the VID register (Reg. 0x43).                                                                                                                                                                                                                                                                                            |
| 9       | TACH3                        | Digital Input (Open Drain). Fan tachometer input to measure speed of Fan 3. Can be reconfigured as an analog input (AIN3) to measure the speed of 2-wire fans.                                                                                                                                                                                                                                                 |
| 10      | PWM2                         | Digital Output (Open Drain). Requires 10 kΩ typical pull-up. Pulse width modulated output to control Fan 2 speed. Can be configured as a high or low frequency drive.                                                                                                                                                                                                                                          |
|         | $\overline{\text{SMBALERT}}$ | Digital Output (Open Drain). This pin can be reconfigured as an $\overline{\text{SMBALERT}}$ interrupt output to signal out-of-limit conditions.                                                                                                                                                                                                                                                               |
| 11      | TACH1                        | Digital Input (Open Drain). Fan tachometer input to measure speed of Fan 1. Can be reconfigured as an analog input (AIN1) to measure the speed of 2-wire fans.                                                                                                                                                                                                                                                 |
| 12      | TACH2                        | Digital Input (Open Drain). Fan tachometer input to measure speed of Fan 2. Can be reconfigured as an analog input (AIN2) to measure the speed of 2-wire fans.                                                                                                                                                                                                                                                 |
| 13      | PWM3                         | Digital I/O (Open Drain). Pulse width modulated output to control speed of Fan 3 and Fan 4. Requires 10 kΩ typical pull-up. Can be configured as a high or low frequency drive.                                                                                                                                                                                                                                |
| 14      | TACH4                        | Digital Input (Open Drain). Fan tachometer input to measure speed of Fan 4. Can be reconfigured as an analog input (AIN4) to measure the speed of 2-wire fans.                                                                                                                                                                                                                                                 |
|         | GPIO                         | General Purpose Open Drain Digital I/O.                                                                                                                                                                                                                                                                                                                                                                        |
|         | $\overline{\text{THERM}}$    | Alternatively, the pin can be reconfigured as a bidirectional $\overline{\text{THERM}}$ pin. Can be used to time and monitor assertions on the $\overline{\text{THERM}}$ input. For example, this pin can be connected to the PROCHOT output of an Intel Pentium 4 processor or to the output of a trip point temperature sensor. This pin can also be used as an output to signal overtemperature conditions. |
|         | $\overline{\text{SMBALERT}}$ | Digital Output (Open Drain). This pin can be reconfigured as an $\overline{\text{SMBALERT}}$ interrupt output to signal out-of-limit conditions.                                                                                                                                                                                                                                                               |
| 15      | D2-                          | Cathode Connection to Second Thermal Diode.                                                                                                                                                                                                                                                                                                                                                                    |
| 16      | D2+                          | Anode Connection to Second Thermal Diode.                                                                                                                                                                                                                                                                                                                                                                      |

## PRODUCT DESCRIPTION

The ADT7468 is a complete thermal monitor and multiple fan controller for any system requiring thermal monitoring and cooling. The device communicates with the system via a serial system management bus. The serial bus controller has a serial data line for reading and writing addresses and data (Pin 1), and an input line for the serial clock (Pin 2). All control and programming functions for the ADT7468 are performed over the serial bus. In addition, a pin can be reconfigured as an SMBALERT output to signal out-of-limit conditions.

### COMPARISON BETWEEN ADT7463 AND ADT7468

The ADT7468 is an upgrade to the ADT7463. The ADT7468 and ADT7463 are almost pin and register map compatible. The ADT7468 and ADT7463 have the following differences:

1. On the ADT7468, the PWM drive signals can be configured as either high frequency or low frequency drives. The low frequency option is programmable between 10 Hz and 100 Hz. The high frequency option is 22.5 kHz. On the ADT7463, only the low frequency option is available.
2. Once the  $V_{CC}$  is powered up, monitoring of temperature and fan speeds is enabled on the ADT7468 when  $V_{CCP}$  is powered up, or if  $V_{CCP}$  is never powered up, when the first SMBus transaction with the ADT7468 is completed. On the ADT7463, the STRT bit in Configuration Register 1 must be set to enable monitoring.
3. The fans are switched off by default on power-up on the ADT7468. On the ADT7463, the fans run at full speed on power-up.

Fail-safe cooling is provided on the ADT7468 in that, if the measured temperature exceeds the THERM limit (100°C), the fans run at full speed.

Fail-safe cooling is also provided 4.6 s after  $V_{CCP}$  is powered up. See Figure 48. The fans go to full speed, if the ADT7468 has not been addressed via the SMBus within 4.6 s of when the  $V_{CCP}$  is powered up. This protects the system in the event that the SMBus fails. The ADT7468 can be programmed at any time, either before or after the 4.6 s has elapsed, and it behaves as programmed. If  $V_{CCP}$  is never powered up, fail-safe cooling is effectively disabled. If  $V_{CCP}$  is disabled, writing to the ADT7468 at any time causes the ADT7468 to operate normally.

4. Series resistance cancellation (SRC) is provided on the remote temperature channels on the ADT7468, but not on the ADT7463. SRC automatically cancels linear offset introduced by a series resistance between the thermal diode and the sensor.

5. The ADT7468 has an extended temperature measurement range. The measurement range goes from  $-64^{\circ}\text{C}$  to  $+191^{\circ}\text{C}$ . On the ADT7463, the measurement range is from  $-127^{\circ}\text{C}$  to  $+127^{\circ}\text{C}$ . This means that the ADT7468 can measure higher temperatures. The ADT7468 also includes the ADT7463 temperature range; the temperature measurement range can be switched by setting Bit 0 of Configuration Register 5.
6. The ADT7468 maximum fan speed (% duty cycle) in the automatic fan speed control loop can be programmed. The maximum fan speed is 100% duty cycle on the ADT7463 and is not programmable.
7. The offset register in the ADT7468 is programmable up to  $\pm 64^{\circ}\text{C}$  with  $0.50^{\circ}\text{C}$  resolution. The offset register of the ADT7463 is programmable up to  $\pm 32^{\circ}\text{C}$  with  $0.25^{\circ}\text{C}$  resolution.
8.  $V_{CCP}$  is monitored on Pin 23 of the ADT7468 and can be used to set the threshold for THERM (PROCHOT) (2/3 of  $V_{CCP}$ ). The threshold for THERM (PROCHOT) is set at  $V_{IH} = 1.7\text{ V}$  and  $V_{IL} = 0.8\text{ V}$  on the ADT7463.
9. On the ADT7463, Pin 22 can be reconfigured as SMBus ALERT. This is not available on the ADT7468; instead, SMBALERT can be enabled on Pin 14.
10. A GPIO can also be made available on Pin 14 on the ADT7468. This is not available on the ADT7463. Set the GPIO polarity and direction in Configuration Register 5. The GPIO status bit is Bit 5 of Status Register 2 (shared with TACH4 and THERM, because only one can be enabled at a time).
11. The ADT7463 has three possible SMBus addresses, which are selectable using the address select and address enable pins. The ADT7468 has one SMBus address available at Address 0x2E.

Due to the inclusion of extra functionality, the register map has changed, including an additional configuration register: Configuration Register 5 at Address 0x7C.

### Configuration Register 5

**Bit 0:** If Bit 0 is set to 1, the ADT7468 is backward compatible temperature-wise with the ADT7463. Measurements,  $T_{MIN}$  calibration circuit, fan control, etc., work in the range  $-127^{\circ}\text{C}$  to  $+127^{\circ}\text{C}$ . Also, care should be taken in reprogramming the temperature limits ( $T_{MIN}$ , operating point, THERM limits) to their desired twos complement value, because the power-on default for them is at Offset 64. The extended temperature range is  $-64^{\circ}\text{C}$  to  $191^{\circ}\text{C}$ . The default is 1, which is in the  $-64^{\circ}\text{C}$  to  $+191^{\circ}\text{C}$  temperature range.

**Bit 1** = 0 is the high frequency (22.5 kHz) fan drive signal.

**Bit 1** = 1 switches the fan drive to low frequency PWM, programmable between 10 Hz and 100 Hz, the same as the ADT7463. The default = 0 = HF PWM.

**Bit 2** sets the direction for the GPIO: 0 = input, 1 = output.

**Bit 3** sets the GPIO polarity: 0 = active low, 1 = active high.

## HOW TO SET THE FUNCTIONALITY OF PIN 14

Pin 14 on the ADT7468 has four possible functions: SMBALERT, THERM, GPIO, and TACH4. The user chooses the required functionality by setting Bit 0 and Bit 1 of Configuration Register 4 at Address 0x7D.

**Table 4. Pin 14 Settings**

| Bit 0 | Bit 1 | Function |
|-------|-------|----------|
| 00    |       | TACH4    |
| 01    |       | THERM    |
| 10    |       | SMBALERT |
| 11    |       | GPIO     |

## RECOMMENDED IMPLEMENTATION

Configuring the ADT7468 as in Figure 15 allows the system designer to use the following features:

- Two PWM outputs for fan control of up to three fans (the front and rear chassis fans are connected in parallel).
- Three TACH fan speed measurement inputs.
- $V_{CC}$  measured internally through Pin 3.
- CPU temperature measured using Remote 1 temperature channel.
- Ambient temperature measured through Remote 2 temperature channel.
- Bidirectional THERM pin. This feature allows Intel Pentium 4 PROCHOT monitoring and can function as an overtemperature THERM output. It can alternatively be programmed as an SMBALERT system interrupt output.

## SERIAL BUS INTERFACE

On PCs and servers, control of the ADT7468 is carried out using the serial system management bus (SMBus). The ADT7468 is connected to this bus as a slave device, under the control of a master controller, which is usually (but not necessarily) the ICH.

The ADT7468 has a fixed 7-bit serial bus address of 0101110 or 0x2E. The read/write bit must be added to get the 8-bit address (01011100 or 0x5C). Data is sent over the serial bus in sequences of nine clock pulses: eight bits of data followed by an acknowledge bit from the slave device. Transitions on the data line must occur during the low period of the clock signal and remain stable during the high period, because a low-to-high transition when the clock is high might be interpreted as a stop signal. The number of data bytes that can be transmitted over the serial bus in a single read or write operation is limited only by what the master and slave devices can handle.

When all data bytes have been read or written, stop conditions are established. In write mode, the master pulls the data line high during the tenth clock pulse to assert a stop condition. In read mode, the master device overrides the acknowledge bit by pulling the data line high during the low period before the ninth clock pulse. This is known as No Acknowledge. The master then takes the data line low during the low period before the tenth clock pulse, and then high during the tenth clock pulse to assert a stop condition.

Any number of bytes of data can be transferred over the serial bus in one operation, but it is not possible to mix read and write in one operation, because the type of operation is determined at the beginning and cannot subsequently be changed without starting a new operation.

In the ADT7468, write operations contain either one or two bytes, and read operations contain one byte and perform the following functions. To write data to one of the device data registers or read data from it, the address pointer register must be set so that the correct data register is addressed, then data can be written into that register or read from it. The first byte of a write operation always contains an address that is stored in the address pointer register. If data is to be written to the device, then the write operation contains a second data byte that is written to the register selected by the address pointer register.

This write operation is illustrated in Figure 16. The device address is sent over the bus, and then R/W is set to 0. This is followed by two data bytes. The first data byte is the address of the internal data register to be written to, which is stored in the address pointer register. The second data byte is the data to be written to the internal data register.

When reading data from a register, there are two possibilities:

- If the ADT7468's address pointer register value is unknown or not the desired value, it must first be set to the correct value before data can be read from the desired data register. This is done by performing a write to the ADT7468 as before, but only the data byte containing the register address is sent, because no data is written to the register. This is shown in Figure 17.

A read operation is then performed consisting of the serial bus address, R/W bit set to 1, followed by the data byte read from the data register. This is shown in Figure 18.

- If the address pointer register is known to be already at the desired address, data can be read from the corresponding data register without first writing to the address pointer register, as shown in Figure 18.

Figure 16. Writing a Register Address to the Address Pointer Register, then Writing Data to the Selected Register

Figure 17. Writing to the Address Pointer Register Only

Figure 18. Reading Data from a Previously Selected Register

It is possible to read a data byte from a data register without first writing to the address pointer register, if the address pointer register is already at the correct value. However, it is not possible to write data to a register without writing to the address pointer register, because the first data byte of a write is always written to the address pointer register.

In addition to supporting the send byte and receive byte protocols, the ADT7468 also supports the read byte protocol. (see *System Management Bus Specifications Rev. 2* for more information. This document is available from Intel.)

If several read or write operations must be performed in succession, the master can send a repeat start condition instead of a stop condition to begin a new operation.

## WRITE OPERATIONS

The SMBus specification defines several protocols for different types of read and write operations. The ones used in the ADT7468 are discussed below. The following abbreviations are used in the diagrams:

S – START  
P – STOP  
R – READ  
W – WRITE  
A – ACKNOWLEDGE  
 $\bar{A}$  – NO ACKNOWLEDGE

The ADT7468 uses the following SMBus write protocols.

### Send Byte

In this operation, the master device sends a single command byte to a slave device as follows:

1. The master device asserts a start condition on SDA.

2. The master sends the 7-bit slave address followed by the write bit (low).
3. The addressed slave device asserts ACK on SDA.
4. The master sends a command code.
5. The slave asserts ACK on SDA.
6. The master asserts a stop condition on SDA and the transaction ends.

For the ADT7468, the send byte protocol is used to write a register address to RAM for a subsequent single byte read from the same address. This operation is illustrated in Figure 19.

Figure 19. Setting a Register Address for Subsequent Read

If the master is required to read data from the register immediately after setting up the address, it can assert a repeat start condition immediately after the final ACK and carry out a single byte read without asserting an intermediate stop condition.

### Write Byte

In this operation, the master device sends a command byte and one data byte to the slave device, as follows:

1. The master device asserts a start condition on SDA.
2. The master sends the 7-bit slave address followed by the write bit (low).
3. The addressed slave device asserts ACK on SDA.
4. The master sends a command code.

# ADT7468

5. The slave asserts ACK on SDA.
6. The master sends a data byte.
7. The slave asserts ACK on SDA.
8. The master asserts a stop condition on SDA to end the transaction.

This operation is illustrated in Figure 20.

Figure 20. Single Byte Write to a Register

## READ OPERATIONS

The ADT7468 uses the following SMBus read protocols.

### Receive Byte

This operation is useful when repeatedly reading a single register. The register address must have been set up previously. In this operation, the master device receives a single byte from a slave device as follows:

1. The master device asserts a start condition on SDA.
2. The master sends the 7-bit slave address followed by the read bit (high).
3. The addressed slave device asserts ACK on SDA.
4. The master receives a data byte.
5. The master asserts NO ACK on SDA.
6. The master asserts a stop condition on SDA and the transaction ends.

In the ADT7468, the receive byte protocol is used to read a single byte of data from a register whose address has previously been set by a send byte or write byte operation. This operation is illustrated in Figure 21.

Figure 21. Single Byte Read from a Register

### Alert Response Address

Alert response address (ARA) is a feature of SMBus devices that allows an interrupting device to identify itself to the host when multiple devices exist on the same bus.

The  $\overline{\text{SMBALERT}}$  output can be used as either an interrupt output or an  $\overline{\text{SMBALERT}}$ . One or more outputs can be connected to a common  $\overline{\text{SMBALERT}}$  line connected to the master. If a device's  $\overline{\text{SMBALERT}}$  line goes low, the following procedure occurs:

1.  $\overline{\text{SMBALERT}}$  is pulled low.
2. The master initiates a read operation and sends the alert response address (ARA = 0001 100). This is a general call address that must not be used as a specific device address.
3. The device whose  $\overline{\text{SMBALERT}}$  output is low responds to the alert response address, and the master reads its device address. The address of the device is now known and can be interrogated in the usual way.
4. If more than one device's  $\overline{\text{SMBALERT}}$  output is low, the one with the lowest device address has priority in accordance with normal SMBus arbitration.
5. Once the ADT7468 has responded to the alert response address, the master must read the status registers and the  $\overline{\text{SMBALERT}}$  is cleared only if the error condition has gone away.

## SMBUS TIMEOUT

The ADT7468 includes an SMBus timeout feature. If there is no SMBus activity for 35 ms, the ADT7468 assumes that the bus is locked and releases the bus. This prevents the device from locking or holding the SMBus expecting data. Some SMBus controllers cannot handle the SMBus timeout feature, so it can be disabled.

### Configuration Register 1 (Reg. 0x40)

<6> TODIS = 0, SMBus timeout enabled (default).

<6> TODIS = 1, SMBus timeout disabled.

## VOLTAGE MEASUREMENT INPUT

The ADT7468 has four external voltage measurement channels. It can also measure its own supply voltage,  $V_{CC}$ . Pins 20 to 23 can measure 5 V, 12 V, and 2.5 V supplies, and the processor core voltage  $V_{CCP}$  (0 V to 3 V input). The  $V_{CC}$  supply voltage measurement is carried out through the  $V_{CC}$  pin (Pin 4). Setting Bit 7 of Configuration Register 1 (Reg. 0x40) allows a 5 V supply to power the ADT7468 and be measured without overranging the  $V_{CC}$  measurement channel. The 2.5 V input can be used to monitor a chipset supply voltage in computer systems.

## ANALOG-TO-DIGITAL CONVERTER

All analog inputs are multiplexed into the on-chip, successive-approximation, analog-to-digital converter. This has a resolution of 10 bits. The basic input range is 0 V to 2.25 V, but the inputs have built-in attenuators to allow measurement of 2.5 V, 3.3 V, 5 V, 12 V, and the processor core voltage  $V_{CCP}$  without any external components. To allow for the tolerance of these supply voltages, the ADC produces an output of 3/4 full scale (decimal 768 or 300 hex) for the nominal input voltage and so has adequate headroom to cope with overvoltages.

## INPUT CIRCUITRY

The internal structure for the analog inputs is shown in Figure 22. The input circuit consists of an input protection diode, an attenuator, plus a capacitor to form a first-order low-pass filter that gives input immunity to high frequency noise.

Figure 22. Structure of Analog Inputs

## VOLTAGE MEASUREMENT REGISTERS

Reg. 0x20, **2.5 V Reading** = 0x00 default

Reg. 0x21, **V<sub>CCP</sub> Reading** = 0x00 default

Reg. 0x22, **V<sub>CC</sub> Reading** = 0x00 default

Reg. 0x23, **5 V Reading** = 0x00 default

Reg. 0x24, **12 V Reading** = 0x00 default

## VOLTAGE LIMIT REGISTERS

Associated with each voltage measurement channel is a high and low limit register. Exceeding the programmed high or low limit causes the appropriate status bit to be set. Exceeding either limit can also generate SMBALERT interrupts.

Reg. 0x44, **2.5 V Low Limit** = 0x00 default

Reg. 0x45, **2.5 V High Limit** = 0xFF default

Reg. 0x46, **V<sub>CCP</sub> Low Limit** = 0x00 default

Reg. 0x47, **V<sub>CCP</sub> High Limit** = 0xFF default

Reg. 0x48, **V<sub>CC</sub> Low Limit** = 0x00 default

Reg. 0x49, **V<sub>CC</sub> High Limit** = 0xFF default

Reg. 0x4A, **5 V Low Limit** = 0x00 default

Reg. 0x4B, **5 V High Limit** = 0xFF default

Reg. 0x4C, **12 V Low Limit** = 0x00 default

Reg. 0x4D, **12 V High Limit** = 0xFF default

Table 5 shows the input ranges of the analog inputs and output codes of the 10-bit ADC.

When the ADC is running, it samples and converts a voltage input in 0.7 ms and averages 16 conversions to reduce noise; a measurement takes nominally 11 ms.

## VID CODE MONITORING

The ADT7468 has five dedicated voltage ID (VID code) inputs. These are digital inputs that can be read back through the VID register (Reg. 0x43) to determine the processor voltage required or being used in the system. Five VID code inputs support VRM9.x solutions. In addition, Pin 21 (12 V input) can be reconfigured as a sixth VID input to satisfy future VRM requirements.

### VID Code Register (Reg. 0x43)

<0> = **VID0**, reflects logic state of Pin 5.

<1> = **VID1**, reflects logic state of Pin 6.

<2> = **VID2**, reflects logic state of Pin 7.

<3> = **VID3**, reflects logic state of Pin 8.

<4> = **VID4**, reflects logic state of Pin 19.

<5> = **VID5**, reconfigurable 12 V input. This bit reads 0 when Pin 21 is configured as the 12 V input. This bit reflects the logic state of Pin 21 when the pin is configured as VID5.

## VID CODE INPUT THRESHOLD VOLTAGE

The switching threshold for the VID code inputs is approximately 1 V. To enable future compatibility, it is possible to reduce the VID code input threshold to 0.6 V. Bit 6 (THLD) of the VID register (Reg. 0x43) controls the VID input threshold voltage.

### VID CODE REGISTER (Reg. 0x43)

<6> **THLD** = 0, VID switching threshold = 1 V,

$$V_{OL} < 0.8 \text{ V}, V_{IH} > 1.7 \text{ V}, V_{MAX} = 3.3 \text{ V}$$

**THLD** = 1, VID switching threshold = 0.6 V,

$$V_{OL} < 0.4 \text{ V}, V_{IH} > 0.8 \text{ V}, V_{MAX} = 3.3 \text{ V}$$

### Reconfiguring Pin 21 as VID5 Input

Pin 21 can be reconfigured as a sixth VID code input (VID5) for VRM10 compatible systems. Because the pin is configured as VID5, it is not possible to monitor a 12 V supply.

Bit 7 of the VID register (Reg. 0x43) determines the function of Pin 21. System or BIOS software can read the state of Bit 7 to determine whether the system is designed to monitor 12 V or is monitoring a sixth VID input.

# ADT7468

## VID Code Register (Reg. 0x43)

<7> VIDSEL = 0, Pin 21 functions as a 12 V measurement input. Software can read this bit to determine that there are five VID inputs being monitored. Bit 5 of Register 0x43 (VID5) always reads back 0. Bit 0 of Status Register 2 (Reg. 0x42) reflects 12 V out-of-limit measurements.

VIDSEL = 1, Pin 21 functions as the sixth VID code input (VID5). Software can read this bit to determine that there are six VID inputs being monitored. Bit 5 of Register 0x43 reflects the logic state of Pin 21. Bit 0 of Status Register 2 (Reg. 0x42) reflects VID code changes.

## VID CODE CHANGE DETECT FUNCTION

The ADT7468 has a VID code change detect function. When Pin 21 is configured as the VID5 input, VID code changes can be detected and reported back by the ADT7468. Bit 0 of Status Register 2 (Reg. 0x42) is the 12 V/VC bit and denotes a VID change when set. The VID code change bit is set when the logic states on the VID inputs are different than they were 11  $\mu$ s previously. The change of VID code can be used to generate an SMBALERT interrupt. If an SMBALERT interrupt is not required, Bit 0 of Interrupt Mask Register 2 (Reg. 0x75), when set, prevents SMBALERTs from occurring on VID code changes.

### Status Register 2 (Reg. 0x42)

<0> 12V/VC = 0, if Pin 21 is configured as VID5, then Logic 0 denotes no change in VID code within the last 11  $\mu$ s.

<0> 12V/VC = 1, if Pin 21 is configured as VID5, then Logic 1 means that a change has occurred on the VID code inputs within the last 11  $\mu$ s. An SMBALERT is generated, if this function is enabled.

## ADDITIONAL ADC FUNCTIONS FOR VOLTAGE MEASUREMENTS

A number of other functions are available on the ADT7468 to offer the system designer increased flexibility.

### Turn-Off Averaging

For each voltage measurement read from a value register, 16 readings have actually been made internally and the results averaged before being placed into the value register. For

instances where faster conversions are needed, setting Bit 4 of Configuration Register 2 (Reg. 0x73) turns averaging off. This effectively gives a reading 16 times faster (0.7 ms), but the reading may be noisier.

### Bypass Voltage Input Attenuator

Setting Bit 5 of Configuration Register 2 (Reg. 0x73) removes the attenuation circuitry from the 2.5 V,  $V_{CCP}$ ,  $V_{CC}$ , 5 V, and 12 V inputs. This allows the user to directly connect external sensors or rescale the analog voltage measurement inputs for other applications. The input range of the ADC without the attenuators is 0 V to 2.25 V.

### Single-Channel ADC Conversion

Setting Bit 6 of Configuration Register 2 (Reg. 0x73) places the ADT7468 into single-channel ADC conversion mode. In this mode, the ADT7468 can be made to read a single voltage channel only. If the internal ADT7468 clock is used, the selected input is read every 0.7 ms. The appropriate ADC channel is selected by writing to Bits <7:5> of the TACH1 minimum high byte register (0x55).

| Bits <7:5> Reg. 0x55 | Channel Selected     |
|----------------------|----------------------|
| 000                  | 2.5 V                |
| 001                  | $V_{CCP}$            |
| 010                  | $V_{CC}$             |
| 011                  | 5 V                  |
| 100                  | 12 V                 |
| 101                  | Remote 1 Temperature |
| 110                  | Local Temperature    |
| 111                  | Remote 2 Temperature |

### Configuration Register 2 (Reg. 0x73)

<4> = 1, averaging off.

<5> = 1, bypass input attenuators.

<6> = 1, single-channel convert mode.

### TACH1 Minimum High Byte (Reg. 0x55)

<7:5> Selects ADC channel for single-channel convert mode.

Table 5. 10-Bit A/D Output Code vs.  $V_{IN}$ 

| Input Voltage   |               |                                       |               |               | A/D Output      |                  |
|-----------------|---------------|---------------------------------------|---------------|---------------|-----------------|------------------|
| 12 $V_{IN}$     | 5 $V_{IN}$    | $V_{CC}$ (3.3 $V_{IN}$ ) <sup>1</sup> | 2.5 $V_{IN}$  | $V_{CCP}$     | Decimal         | Binary (10 Bits) |

<sup>1</sup> The  $V_{CC}$  output codes listed assume that  $V_{CC}$  is 3.3 V. If  $V_{CC}$  input is reconfigured for 5 V operation (by setting Bit 7 of Configuration Register 1), then the  $V_{CC}$  output codes are the same as for the 5  $V_{IN}$  column.

## TEMPERATURE MEASUREMENT METHOD

A simple method of measuring temperature is to exploit the negative temperature coefficient of a diode, measuring the base-emitter voltage ( $V_{BE}$ ) of a transistor, operated at constant current. Unfortunately, this technique requires calibration to null out the effect of the absolute value of  $V_{BE}$ , which varies from device to device.

The technique used in the ADT7468 is to measure the change in  $V_{BE}$  when the device is operated at three different currents. Previous devices have used only two operating currents, but the use of a third current allows automatic cancellation of resistances in series with the external temperature sensor.

Figure 24 shows the input signal conditioning used to measure the output of an external temperature sensor. This figure shows the external sensor as a substrate transistor, but it could equally be a discrete transistor. If a discrete transistor is used, the collector is not grounded and should be linked to the base. To prevent ground noise from interfering with the measurement, the more negative terminal of the sensor is not referenced to ground, but is biased above ground by an internal diode at the D<sup>-</sup> input. C1 can optionally be added as a noise filter (recommended maximum value 1000 pF). However, a better option in noisy environments is to add a filter, as described in the Noise Filtering section.

### Local Temperature Measurement

The ADT7468 contains an on-chip band gap temperature sensor whose output is digitized by the on-chip 10-bit ADC. The 8-bit MSB temperature data is stored in the local temperature register (Address 26h). Because both positive and negative temperatures can be measured, the temperature data is stored in Offset 64 format or twos complement format, as shown in Table 6 and Table 7. Theoretically, the temperature sensor and ADC can measure temperatures from  $-128^{\circ}\text{C}$  to  $+127^{\circ}\text{C}$  (or  $-61^{\circ}\text{C}$  to  $+191^{\circ}\text{C}$  in the extended temperature range) with a resolution of  $0.25^{\circ}\text{C}$ . However, this exceeds the operating temperature range of the device, so local temperature measurements outside the ADT7468 operating temperature range are not possible.

### Remote Temperature Measurement

The ADT7468 can measure the temperature of two remote diode sensors or diode-connected transistors connected to Pins 17 and 18, or 15 and 16.

The forward voltage of a diode or diode-connected transistor operated at a constant current exhibits a negative temperature coefficient of about  $-2\text{ mV}/^{\circ}\text{C}$ . Unfortunately, the absolute value of  $V_{BE}$  varies from device to device and individual calibration is required to null this out, so the technique is unsuitable for mass production. The technique used in the ADT7468 is to measure the change in  $V_{BE}$  when the device is operated at three different currents.

This is given by

$$\Delta V_{BE} = KT / q \times \ln(N)$$

where:

$K$  is Boltzmann's constant.

$q$  is the charge on the carrier.

$T$  is the absolute temperature in Kelvin.

$N$  is the ratio of the two currents.

Figure 23 shows the input signal conditioning used to measure the output of a remote temperature sensor. This figure shows the external sensor as a substrate transistor, provided for temperature monitoring on some microprocessors. It could also be a discrete transistor such as a 2N3904/2N3906.

Figure 23. Signal Conditioning for Remote Diode Temperature Sensors

If a discrete transistor is used, the collector is not grounded and should be linked to the base. If a PNP transistor is used, the base is connected to the D<sup>-</sup> input and the emitter to the D<sup>+</sup> input. If an NPN transistor is used, the emitter is connected to the D<sup>-</sup> input and the base to the D<sup>+</sup> input. Figure 25 and Figure 26 show how to connect the ADT7468 to an NPN or PNP transistor for temperature measurement. To prevent ground noise from interfering with the measurement, the more negative terminal of the sensor is not referenced to ground, but is biased above ground by an internal diode at the D<sup>-</sup> input.

To measure  $\Delta V_{BE}$ , the operating current through the sensor is switched among three related currents. Shown in Figure 23,  $N1 \times I$  and  $N2 \times I$  are different multiples of the current  $I$ . The currents through the temperature diode are switched between  $I$  and  $N1 \times I$ , giving  $\Delta V_{BE1}$ , and then between  $I$  and  $N2 \times I$ , giving  $\Delta V_{BE2}$ . The temperature can then be calculated using the two  $\Delta V_{BE}$  measurements. This method can also cancel the effect of any series resistance on the temperature measurement.

The resulting  $\Delta V_{BE}$  waveforms are passed through a 65 kHz low-pass filter to remove noise and then to a chopper-stabilized amplifier. This amplifies and rectifies the waveform to produce a DC voltage proportional to  $\Delta V_{BE}$ . The ADC digitizes this voltage, and a temperature measurement is produced. To reduce the effects of noise, digital filtering is performed by averaging the results of 16 measurement cycles.

The results of remote temperature measurements are stored in 10-bit, two's complement format, as illustrated in Table 6. The extra resolution for the temperature measurements is held in the Extended Resolution Register 2 (Reg. 0x77). This gives temperature readings with a resolution of 0.25°C.

### Noise Filtering

For temperature sensors operating in noisy environments, previous practice was to place a capacitor across the D+ and D– pins to help combat the effects of noise. However, large capacitances affect the accuracy of the temperature measurement, leading to a recommended maximum capacitor value of 1000 pF. This capacitor reduces the noise, but does not eliminate it, making use of the sensor difficult in a very noisy environment.

The ADT7468 has a major advantage over other devices for eliminating the effects of noise on the external sensor. Using the series resistance cancellation feature, a filter can be constructed between the external temperature sensor and the part. The effect of any filter resistance seen in series with the remote sensor is automatically canceled from the temperature result.

The construction of a filter allows the ADT7468 and the remote temperature sensor to operate in noisy environments. Figure 24 shows a low-pass R-C-R filter, with the following values :

$R = 100\ \Omega$ ,  $C = 1\ \text{nF}$ .

This filtering reduces both common-mode noise and differential noise.

Figure 24. Filter Between Remote Sensor and ADT7468

### SERIES RESISTANCE CANCELLATION

Parasitic resistance to the ADT7468 D+ and D– inputs (seen in series with the remote diode) is caused by a variety of factors, including PCB track resistance and track length. This series resistance appears as a temperature offset in the remote sensor's temperature measurement. This error typically causes a 0.5°C offset per  $\Omega$  of parasitic resistance in series with the remote diode.

The ADT7468 automatically cancels out the effect of this series resistance on the temperature reading, giving a more accurate result, without the need for user characterization of this resistance. The ADT7468 is designed to automatically cancel, typically, up to 3 k $\Omega$  of resistance. By using an advanced temperature measurement method, this is transparent to the user. This feature allows resistances to be added to the sensor path to produce a filter, allowing the part to be used in noisy environments. See the Noise Filtering section for details.

### FACTORS AFFECTING DIODE ACCURACY

#### Remote Sensing Diode

The ADT7468 is designed to work with either substrate transistors built into processors or with discrete transistors. Substrate transistors are generally PNP types with the collector connected to the substrate. Discrete types can be either PNP or NPN transistors connected as a diode (base-short to the collector). If an NPN transistor is used, the collector and base are connected to D+ and the emitter to D–. If a PNP transistor is used, the collector and base are connected to D– and the emitter is connected to D+.

To reduce the error due to variations in both substrate and discrete transistors, a number of factors should be taken into consideration:

- The ideality factor,  $n_f$ , of the transistor is a measure of the deviation of the thermal diode from ideal behavior. The ADT7468 is trimmed for an  $n_f$  value of 1.008. Use the following equation to calculate the error introduced at a temperature  $T$  (°C), when using a transistor whose  $n_f$  does not equal 1.008. See the processor data sheet for the  $n_f$  values.

$$\Delta T = (n_f - 1.008) \times (273.15\ \text{K} + T)$$

To factor this in, the user can write the  $\Delta T$  value to the offset register. The ADT7468 then automatically adds it to or subtracts it from the temperature measurement.

- Some CPU manufacturers specify the high and low current levels of the substrate transistors. The high current level of the ADT7468,  $I_{\text{HIGH}}$ , is 96  $\mu\text{A}$  and the low level current,  $I_{\text{LOW}}$ , is 6  $\mu\text{A}$ . If the ADT7468 current levels do not match the current levels specified by the CPU manufacturer, it might be necessary to remove an offset. The CPU's data sheet advises whether this offset needs to be removed and how to calculate it. This offset can be programmed to the offset register. It is important to note that, if more than one offset must be considered, the algebraic sum of these offsets must be programmed to the offset register.

If a discrete transistor is used with the ADT7468, the best accuracy is obtained by choosing devices according to the following criteria:

- Base-emitter voltage greater than 0.25 V at 6  $\mu\text{A}$ , at the highest operating temperature.
- Base-emitter voltage less than 0.95 V at 100  $\mu\text{A}$ , at the lowest operating temperature.
- Base resistance less than 100  $\Omega$ .
- Small variation in  $h_{\text{FE}}$  (say 50 to 150) that indicates tight control of  $V_{\text{BE}}$  characteristics.

# ADT7468

Transistors, such as 2N3904, 2N3906, or equivalents in SOT-23 packages, are suitable devices to use.

**Table 6. Temperature Data Format**

| Temperature | Digital Output (10-Bit) <sup>1</sup> |
|-------------|--------------------------------------|
| -128°C      | 1000 0000 <b>00</b>                  |

| 191°C       | 1111 1111 <b>00</b>                  |

<sup>1</sup> Bold numbers denote 2 LSB of measurement in Extended Resolution Register 2 (Reg. 0x77) with 0.25°C resolution.

Figure 25. Measuring Temperature Using an NPN Transistor

Figure 26. Measuring Temperature Using a PNP Transistor

## Nulling Out Temperature Errors

As CPUs run faster, it is getting more difficult to avoid high frequency clocks when routing the D+/D- traces around a system board. Even when recommended layout guidelines are followed, some temperature errors may still be attributable to noise coupled onto the D+/D- lines. Constant high frequency noise usually attenuates or increases temperature measurements by a linear, constant value.

The ADT7468 has temperature offset registers at Addresses 0x70, 0x72 for the Remote 1 and Remote 2 temperature channels. By doing a one-time calibration of the system, the user can determine the offset caused by system board noise and null it out using the offset registers. The offset registers automatically add an Offset 64/twos complement 8-bit reading to every temperature measurement. The LSBs add 0.5°C offset to the temperature reading so the 8-bit register effectively allows temperature offsets of up to ±64°C with a resolution of 0.5°C. This ensures that the readings in the temperature measurement registers are as accurate as possible.

## Temperature Offset Registers

Reg. 0x70, **Remote 1 Temperature Offset** = 0x00 (0°C default)

Reg. 0x71, **Local Temperature Offset** = 0x00 (0°C default)

Reg. 0x72, **Remote 2 Temperature Offset** = 0x00 (0°C default)

## ADT7463/ADT7468 Backwards Compatible Mode

By setting Bit 1 of Configuration Register 5 (0x7C), all temperature measurements are stored in the Zone Temp value registers (0x25, 0x26, and 0x27) in twos complement in the range -64°C to +127°C (the ADT7468 still makes calculations based on the Offset 64 extended range and clamps the results, if necessary.)

The temperature limits must be reprogrammed in twos complement. If a twos complement temperature below -63°C is entered, the temperature is clamped to -63°C. In this mode, the diode fault condition remains -128°C = 1000 0000, while in the extended temperature range (-64°C to +191°C), the fault condition is represented by -64°C = 0000 0000.

## Temperature Measurement Registers

Reg. 0x25, **Remote 1 Temperature**

Reg. 0x26, **Local Temperature**

Reg. 0x27, **Remote 2 Temperature**

Reg. 0x77, **Extended Resolution 2** = 0x00 default

<7:6> **TDM2**, Remote 2 temperature LSBs.

<5:4> **LTMP**, local temperature LSBs.

<3:2> **TDM1**, Remote 1 temperature LSBs.

### Temperature Measurement Limit Registers

Associated with each temperature measurement channel are high and low limit registers. Exceeding the programmed high or low limit causes the appropriate status bit to be set. Exceeding either limit can also generate SMBALERT interrupts.

Reg. 0x4E, **Remote 1 Temperature Low Limit** = 0x01 default

Reg. 0x4F, **Remote 1 Temperature High Limit** = 0x7F default

Reg. 0x50, **Local Temperature Low Limit** = 0x01 default

Reg. 0x51, **Local Temperature High Limit** = 0x7F default

Reg. 0x52, **Remote 2 Temperature Low Limit** = 0x01 default

Reg. 0x53, **Remote 2 Temperature High Limit** = 0x7F default

### Reading Temperature from the ADT7468

It is important to note that temperature can be read from the ADT7468 as an 8-bit value (with 1°C resolution) or as a 10-bit value (with 0.25°C resolution). If only 1°C resolution is required, the temperature readings can be read back at any time and in no particular order.

If the 10-bit measurement is required, this involves a 2-register read for each measurement. The extended resolution register (Reg. 0x77) should be read first. This causes all temperature reading registers to be frozen until all temperature reading registers have been read from. This prevents an MSB reading from being updated while its two LSBs are being read and vice versa.

## ADDITIONAL ADC FUNCTIONS FOR TEMPERATURE MEASUREMENT

A number of other functions are available on the ADT7468 to offer the system designer increased flexibility.

### Turn-Off Averaging

For each temperature measurement read from a value register, 16 readings have actually been made internally and the results averaged before being placed into the value register. Sometimes it is necessary to take a very fast measurement. Setting Bit 4 of Configuration Register 2 (Reg. 0x73) turns averaging off.

**Table 8. Conversion Time with Averaging Disabled**

| Channel              | Measurement Time |
|----------------------|------------------|
| Voltage Channels     | 0.7 ms           |
| Remote Temperature 1 | 7 ms             |
| Remote Temperature 2 | 7 ms             |
| Local Temperature    | 1.3 ms           |

**Table 9. Conversion Time with Averaging Enabled**

| Channel            | Measurement Time |
|--------------------|------------------|
| Voltage Channels   | 11 ms            |
| Remote Temperature | 39 ms            |
| Local Temperature  | 12 ms            |

### Single-Channel ADC Conversions

Setting Bit 6 of Configuration Register 2 (Reg. 0x73) places the ADT7468 into single-channel ADC conversion mode. In this mode, the ADT7468 can be made to read a single temperature channel only. The appropriate ADC channel is selected by writing to Bits <7:5> of the TACH1 minimum high byte register (0x55).

**Table 10. Channel Selection**

| Bits <7:5> Reg. 0x55 | Channel Selected     |
|----------------------|----------------------|
| 101                  | Remote 1 temperature |
| 110                  | Local temperature    |
| 111                  | Remote 2 temperature |

### Configuration Register 2 (Reg. 0x73)

<4> = 1, averaging off.

<6> = 1, single-channel convert mode.

### TACH1 Minimum High Byte (Reg. 0x55)

<7:5> selects ADC channel for single-channel convert mode.

### Overtemperature Events

Overtemperature events on any of the temperature channels can be detected and dealt with automatically in automatic fan speed control mode. Register 0x6A to Register 0x6C are the  $\overline{\text{THERM}}$  temperature limits. When a temperature exceeds its  $\overline{\text{THERM}}$  temperature limit, all PWM outputs run at the maximum PWM duty cycle (Reg. 0x38, Reg. 0x39, and Reg. 0x3A). This effectively runs the fans at the fastest allowed speed. The fans stay running at this speed until the temperature drops below  $\overline{\text{THERM}}$  minus hysteresis. (This can be disabled by setting the boost bit in Configuration Register 3, Bit 2, Reg. 0x78.) The hysteresis value for that  $\overline{\text{THERM}}$  temperature limit is the value programmed into Reg. 0x6D and Reg. 0x6E (hysteresis registers). The default hysteresis value is 4°C.

Figure 27.  $\overline{\text{THERM}}$  Temperature Limit Operation

## LIMITS, STATUS REGISTERS, AND INTERRUPTS

### LIMIT VALUES

Associated with each measurement channel on the ADT7468 are high and low limits. These can form the basis of system status monitoring; a status bit can be set for any out-of-limit condition and detected by polling the device. Alternatively, SMBALERT interrupts can be generated to flag a processor or microcontroller of out-of-limit conditions.

#### 8-Bit Limits

The following is a list of 8-bit limits on the ADT7468.

#### Voltage Limit Registers

Reg. 0x44, **2.5 V Low Limit** = 0x00 default

Reg. 0x45, **2.5 V High Limit** = 0xFF default

Reg. 0x46, **V<sub>CCP</sub> Low Limit** = 0x00 default

Reg. 0x47, **V<sub>CCP</sub> High Limit** = 0xFF default

Reg. 0x48, **V<sub>CC</sub> Low Limit** = 0x00 default

Reg. 0x49, **V<sub>CC</sub> High Limit** = 0xFF default

Reg. 0x4A, **5 V Low Limit** = 0x00 default

Reg. 0x4B, **5 V High Limit** = 0xFF default

Reg. 0x4C, **12 V Low Limit** = 0x00 default

Reg. 0x4D, **12 V High Limit** = 0xFF default

Reg. 0x46, **V<sub>CCP</sub> Low Limit** = 0x00 default

Reg. 0x47, **V<sub>CCP</sub> High Limit** = 0xFF default

Reg. 0x48, **V<sub>CC</sub> Low Limit** = 0x00 default

Reg. 0x49, **V<sub>CC</sub> High Limit** = 0xFF default

#### Temperature Limit Registers

Reg. 0x4E, **Remote 1 Temperature Low Limit** = 0x01 default

Reg. 0x4F, **Remote 1 Temperature High Limit** = 0x7F default

Reg. 0x6A, **Remote 1  $\overline{\text{THERM}}$  Limit** = 0x64 default

Reg. 0x50, **Local Temperature Low Limit** = 0x01 default

Reg. 0x51, **Local Temperature High Limit** = 0x7F default

Reg. 0x6B, **Local  $\overline{\text{THERM}}$  Limit** = 0x64 default

Reg. 0x52, **Remote 2 Temperature Low Limit** = 0x01 default

Reg. 0x53, **Remote 2 Temperature High Limit** = 0x7F default

Reg. 0x6C, **Remote 2  $\overline{\text{THERM}}$  Limit** = 0x64 default

#### $\overline{\text{THERM}}$ Limit Register

Reg. 0x7A,  **$\overline{\text{THERM}}$  Limit** = 0x00 default

#### 16-Bit Limits

The fan TACH measurements are 16-bit results. The fan TACH limits are also 16 bits, consisting of a high byte and low byte. Because fans running under speed or stalled are normally the only conditions of interest, only high limits exist for fan TACHs. Because the fan TACH period is actually being measured, exceeding the limit indicates a slow or stalled fan.

#### Fan Limit Registers

Reg. 0x54, **TACH1 Minimum Low Byte** = 0x00 default

Reg. 0x55, **TACH1 Minimum High Byte** = 0x00 default

Reg. 0x56, **TACH2 Minimum Low Byte** = 0x00 default

Reg. 0x57, **TACH2 Minimum High Byte** = 0x00 default

Reg. 0x58, **TACH3 Minimum Low Byte** = 0x00 default

Reg. 0x59, **TACH3 Minimum High Byte** = 0x00 default

Reg. 0x5A, **TACH4 Minimum Low Byte** = 0x00 default

Reg. 0x5B, **TACH4 Minimum High Byte** = 0x00 default

#### Out-of-Limit Comparisons

Once all limits have been programmed, the ADT7468 can be enabled for monitoring. The ADT7468 measures all voltage and temperature measurements in round-robin format and sets the appropriate status bit for out-of-limit conditions. TACH measurements are not part of this round-robin cycle. Comparisons are done differently depending on whether the measured value is being compared to a high or low limit.

**High Limit: > Comparison Performed**

**Low Limit:  $\leq$  Comparison Performed**

Voltage and temperature channels use a window comparator for error detecting and, therefore, have high and low limits. Fan speed measurements use only a low limit. This fan limit is needed only in manual fan control mode.

#### Analog Monitoring Cycle Time

The analog monitoring cycle begins when a 1 is written to the start bit (Bit 0) of Configuration Register 1 (Reg. 0x40). By default, the ADT7463 powers up with this bit set. The ADC measures each analog input in turn and, as each measurement is completed, the result is automatically stored in the appropriate value register. This round-robin monitoring cycle continues unless disabled by writing a 0 to Bit 0 of Configuration Register 1.

As the ADC is normally left to free-run in this manner, the time taken to monitor all the analog inputs is normally not of interest, because the most recently measured value of any input can be read out at any time.

For applications where the monitoring cycle time is important, it can easily be calculated.

The total number of channels measured is

- Four dedicated supply voltage inputs
- Supply voltage ( $V_{CC}$  pin)
- Local temperature
- Two remote temperatures

As mentioned previously, the ADC performs round-robin conversions and takes 11 ms for each voltage measurement, 12 ms for a local temperature reading, and 39 ms for each remote temperature reading. The total monitoring cycle time for averaged voltage and temperature monitoring is, therefore, nominally

$$(5 \times 11) + 12 + (2 \times 39) = 145 \text{ ms}$$

Fan TACH measurements are made in parallel and are not synchronized with the analog measurements in any way.

## STATUS REGISTERS

The results of limit comparisons are stored in Status Registers 1 and 2. The status register bit for each channel reflects the status of the last measurement and limit comparison on that channel. If a measurement is within limits, the corresponding status register bit is cleared to 0. If the measurement is out-of-limits, the corresponding status register bit is set to 1.

The state of the various measurement channels can be polled by reading the status registers over the serial bus. In Bit 7 (OOL) of Status Register 1 (Reg. 0x41), 1 means that an out-of-limit event has been flagged in Status Register 2. This means that the user also needs to read Status Register 2. Alternatively, Pin 10 or Pin 14 can be configured as an SMBALERT output. This hardware interrupt automatically notifies the system supervisor of an out-of-limit condition. Reading the status registers clears the appropriate status bit as long as the error condition that caused the interrupt has cleared. Status register bits are “sticky.” Whenever a status bit is set, indicating an out-of-limit condition, it remains set even if the event that caused it has gone away (until read). The only way to clear the status bit is to read the status register after the event has gone away. Interrupt status mask registers (Reg. 0x74, and Reg. 0x75) allow individual interrupt sources to be masked from causing an SMBALERT. However, if one of these masked interrupt sources goes out-of-limit, its associated status bit is set in the interrupt status registers.

### Status Register 1 (Reg. 0x41)

**Bit 7 (OOL) = 1**, denotes a bit in Status Register 2 is set and Status Register 2 should be read.

**Bit 6 (R2T) = 1**, Remote 2 temperature high or low limit has been exceeded.

**Bit 5 (LT) = 1**, local temperature high or low limit has been exceeded.

**Bit 4 (R1T) = 1**, Remote 1 temperature high or low limit has been exceeded.

**Bit 3 (5 V) = 1**, 5 V high or low limit has been exceeded.

**Bit 2 ( $V_{CC}$ ) = 1**,  $V_{CC}$  high or low limit has been exceeded.

**Bit 1 ( $V_{CCP}$ ) = 1**,  $V_{CCP}$  high or low limit has been exceeded.

**Bit 0 (2.5 V) = 1**, 2.5 V high or low limit has been exceeded.

### Status Register 2 (Reg. 0x42)

**Bit 7 (D2) = 1**, indicates an open or short on D2+/D2– inputs.

**Bit 6 (D1) = 1**, indicates an open or short on D1+/D1– inputs.

**Bit 5 (F4P) = 1**, indicates Fan 4 has dropped below minimum speed. Alternatively, indicates that the  $\overline{\text{THERM}}$  limit has been exceeded, if the  $\overline{\text{THERM}}$  function is used.

**Bit 4 (FAN3) = 1**, indicates Fan 3 has dropped below minimum speed.

**Bit 3 (FAN2) = 1**, indicates Fan 2 has dropped below minimum speed.

**Bit 2 (FAN1) = 1**, indicates Fan 1 has dropped below minimum speed.

**Bit 1 (OVT) = 1**, indicates a  $\overline{\text{THERM}}$  overtemperature limit has been exceeded.

**Bit 0 (12V/VC) = 1**, indicates a 12 V high or low limit has been exceeded. If the VID code change function is used, this bit indicates a change in VID code on the VID0 to VID5 inputs.

### SMBALERT Interrupt Behavior

The ADT7468 can be polled for status, or an SMBALERT interrupt can be generated for out-of-limit conditions. It is important to note how the  $\overline{\text{SMBALERT}}$  output and status bits behave when writing interrupt handler software.

Figure 28.  $\overline{\text{SMBALERT}}$  and Status Bit Behavior

Figure 28 shows how the  $\overline{\text{SMBALERT}}$  output and “sticky” status bits behave. Once a limit is exceeded, the corresponding status bit is set to 1. The status bit remains set until the error condition subsides and the status register is read. The status bits are referred to as “sticky,” because they remain set until read by software. This ensures that an out-of-limit event cannot be missed, if software is polling the device periodically. Note that the  $\overline{\text{SMBALERT}}$  output remains low for the entire duration that a reading is out-of-limit and until the status register has been read. This has implications on how software handles the interrupt.

### Handling $\overline{\text{SMBALERT}}$ Interrupts

To prevent the system from being tied up servicing interrupts, it is recommended to handle the  $\overline{\text{SMBALERT}}$  interrupt as follows:

1. Detect the  $\overline{\text{SMBALERT}}$  assertion.
2. Enter the interrupt handler.
3. Read the status registers to identify the interrupt source.
4. Mask the interrupt source by setting the appropriate mask bit in the interrupt mask registers (Reg. 0x74 and Reg. 0x75).
5. Take the appropriate action for a given interrupt source.
6. Exit the interrupt handler.
7. Periodically poll the status registers. If the interrupt status bit has cleared, reset the corresponding interrupt mask bit to 0. This causes the  $\overline{\text{SMBALERT}}$  output and status bits to behave as shown in Figure 29.

### Masking Interrupt Sources

Interrupt Mask Registers 1 and 2 are located at Addresses 0x74 and 0x75. These allow individual interrupt sources to be masked out to prevent  $\overline{\text{SMBALERT}}$  interrupts. Note that masking an interrupt source prevents only the  $\overline{\text{SMBALERT}}$  output from being asserted; the appropriate status bit is set normally.

Figure 29. How Masking the Interrupt Source Affects  $\overline{\text{SMBALERT}}$  Output

### Interrupt Mask Register 1 (Reg. 0x74)

**Bit 7 (OOL) = 1**, masks  $\overline{\text{SMBALERT}}$  for any alert condition flagged in Status Register 2.

**Bit 6 (R2T) = 1**, masks  $\overline{\text{SMBALERT}}$  for Remote 2 temperature.

**Bit 5 (LT) = 1**, masks  $\overline{\text{SMBALERT}}$  for local temperature.

**Bit 4 (R1T) = 1**, masks  $\overline{\text{SMBALERT}}$  for Remote 1 temperature.

**Bit 3 (5 V) = 1**, masks  $\overline{\text{SMBALERT}}$  for 5 V channel.

**Bit 2 (V<sub>CC</sub>) = 1**, masks  $\overline{\text{SMBALERT}}$  for V<sub>CC</sub> channel.

**Bit 0 (V<sub>CCP</sub>) = 1**, masks  $\overline{\text{SMBALERT}}$  for V<sub>CCP</sub> channel.

### Interrupt Mask Register 2 (Reg. 0x75)

**Bit 7 (D2) = 1**, masks  $\overline{\text{SMBALERT}}$  for Diode 2 errors.

**Bit 6 (D1) = 1**, masks  $\overline{\text{SMBALERT}}$  for Diode 1 errors.

**Bit 5 (FAN4) = 1**, masks  $\overline{\text{SMBALERT}}$  for Fan 4 failure.

If the TACH4 pin is being used as the  $\overline{\text{THERM}}$  input, this bit masks  $\overline{\text{SMBALERT}}$  for a  $\overline{\text{THERM}}$  event.

**Bit 4 (FAN3) = 1**, masks  $\overline{\text{SMBALERT}}$  for Fan 3.

**Bit 3 (FAN2) = 1**, masks  $\overline{\text{SMBALERT}}$  for Fan 2.

**Bit 2 (FAN1) = 1**, masks  $\overline{\text{SMBALERT}}$  for Fan 1.

**Bit 1 (OVT) = 1**, masks  $\overline{\text{SMBALERT}}$  for overtemperature (exceeding  $\overline{\text{THERM}}$  temperature limits).

**Bit 0 (12V/VC) = 1**, masks  $\overline{\text{SMBALERT}}$  for 12 V channel or for a VID code change, depending on the function used.

### Enabling the SMBALERT Interrupt Output

The SMBALERT interrupt function is disabled by default. Pin 10 or Pin 14 can be reconfigured as an SMBALERT output to signal out-of-limit conditions.

**Table 11. Configuring Pin 10 as SMBALERT Output**

| Register                             | Bit Setting                             |
|--------------------------------------|-----------------------------------------|
| Configuration Register 3 (Reg. 0x78) | <0> Pin 10 = ALERT<br><1> Pin 10 = PWM2 |

### Assigning THERM Functionality to a Pin

Pin 14 on the ADT7468 has four possible functions: SMBALERT, THERM, GPIO, and TACH4. The user chooses the required functionality by setting Bit 0 and Bit 1 of Configuration Register 4 at Address 0x7D.

If THERM is enabled (Bit 1, Configuration Register 3 at Address 0x78):

- Pin 20 becomes THERM.
- If Pin 14 is configured as THERM (Bit 0 and Bit 1 of Configuration Register 4 at Address 0x7D), then THERM is enabled on this pin.

If THERM is not enabled:

- Pin 20 becomes a 5 V measurement input.
- If Pin 14 is configured as THERM, then THERM is disabled on this Pin.

**Table 12. Configuring Pin 14**

| Bit 0 | Bit 1 | Function |
|-------|-------|----------|
| 0     | 0     | TACH4    |
| 0     | 1     | THERM    |
| 1     | 0     | SMBALERT |
| 1     | 1     | GPIO     |

### THERM as an Input

When THERM is configured as an input, the user can time assertions on the THERM pin. This can be useful for connecting to the PROCHOT output of a CPU to gauge system performance.

The user can also set up the ADT7468 so that, when the THERM pin is driven low externally, the fans run at 100%. The fans run at 100% for the duration of the time that the THERM pin is pulled low. This is done by setting the BOOST bit (Bit 2) in Configuration Register 3 (Address = 0x78) to 1. This works only if the fan is already running, for example, in manual mode when the current duty cycle is above 0x00, or in automatic mode when the temperature is above  $T_{MIN}$ . If the temperature is

below  $T_{MIN}$  or if the duty cycle in manual mode is set to 0x00, then pulling the THERM low externally has no effect. See Figure 30 for more information.

Figure 30. Asserting THERM Low as an Input in Automatic Fan Speed Control Mode

### THERM TIMER

The ADT7468 has an internal timer to measure THERM assertion time. For example, the THERM input can be connected to the PROCHOT output of a Pentium 4 CPU to measure system performance. The THERM input can also be connected to the output of a trip point temperature sensor.

The timer is started on the assertion of the ADT7468's THERM input and stopped when THERM is unasserted. The timer counts THERM times cumulatively, that is, the timer resumes counting on the next THERM assertion. The THERM timer continues to accumulate THERM assertion times until the timer is read (it is cleared on read) or until it reaches full scale. If the counter reaches full scale, it stops at that reading until cleared.

The 8-bit THERM timer register (Reg. 0x79) is designed such that Bit 0 is set to 1 on the first THERM assertion. Once the cumulative THERM assertion time has exceeded 45.52 ms, Bit 1 of the THERM timer is set and Bit 0 now becomes the LSB of the timer with a resolution of 22.76 ms (see Figure 31).

When using the THERM timer, be aware of the following.

After a THERM timer read (Reg. 0x79):

- The contents of the timer are cleared on read.
- The F4P bit (Bit 5) of Status Register 2 needs to be cleared (assuming that the THERM timer limit has been exceeded).

If the  $\overline{\text{THERM}}$  timer is read during a  $\overline{\text{THERM}}$  assertion, then the following happens:

1. The contents of the timer are cleared.
2. Bit 0 of the  $\overline{\text{THERM}}$  timer is set to 1 (because a  $\overline{\text{THERM}}$  assertion is occurring).
3. The  $\overline{\text{THERM}}$  timer increments from zero.
4. If the  $\overline{\text{THERM}}$  timer limit (Reg. 0x7A) = 0x00, then the F4P bit is set.

## Generating SMBALERT Interrupts from $\overline{\text{THERM}}$ Timer Events

The ADT7468 can generate SMBALERTs when a programmable  $\overline{\text{THERM}}$  timer limit has been exceeded. This allows the system designer to ignore brief, infrequent  $\overline{\text{THERM}}$  assertions, while capturing longer  $\overline{\text{THERM}}$  timer events. Register 0x7A is the  $\overline{\text{THERM}}$  timer limit register. This 8-bit register allows a limit from 0 s (first  $\overline{\text{THERM}}$  assertion) to 5.825 s to be set before an SMBALERT is generated. The  $\overline{\text{THERM}}$  timer value is compared with the contents of the  $\overline{\text{THERM}}$  timer limit register. If the  $\overline{\text{THERM}}$  timer value exceeds the  $\overline{\text{THERM}}$  timer limit value, then the F4P bit (Bit 5) of Status Register 2 is set and an SMBALERT is generated. Note that the F4P bit (Bit 5) of Mask Register 2 (Reg. 0x75) masks out SMBALERTs, if this bit is set to 1; although the F4P bit of Interrupt Status Register 2 still is set, if the  $\overline{\text{THERM}}$  timer limit is exceeded.

Figure 31. Understanding the  $\overline{\text{THERM}}$  Timer

Figure 32 is a functional block diagram of the  $\overline{\text{THERM}}$  timer, limit, and associated circuitry. Writing a value of 0x00 to the  $\overline{\text{THERM}}$  timer limit register (Reg. 0x7A) causes SMBALERT to be generated on the first  $\overline{\text{THERM}}$  assertion. A  $\overline{\text{THERM}}$  timer limit value of 0x01 generates an SMBALERT, once cumulative  $\overline{\text{THERM}}$  assertions exceed 45.52 ms.

Figure 32. Functional Block Diagram of  $\overline{\text{THERM}}$  Monitoring Circuitry

### Configuring the Relevant $\overline{\text{THERM}}$ Behavior

1. Configure the desired pin as the  $\overline{\text{THERM}}$  timer input.

Setting Bit 1 ( $\overline{\text{THERM}}$  timer enable) of Configuration Register 3 (Reg. 0x78) enables the  $\overline{\text{THERM}}$  timer monitoring functionality. This is disabled on Pins 14 and 20 by default.

Setting Bits 0 and 1 (PIN14FUNC) of Configuration Register 4 (Reg. 0x7D) enables  $\overline{\text{THERM}}$  timer output functionality on Pin 20 (Bit 1 of Configuration Register 3,  $\overline{\text{THERM}}$ , must also be set). Pin 14 can also be used as TACH4.

2. Select the desired fan behavior for  $\overline{\text{THERM}}$  timer events.

Assuming that the fans are running, setting Bit 2 (BOOST bit) of Configuration Register 3 (Reg. 0x78) causes all fans to run at 100% duty cycle whenever  $\overline{\text{THERM}}$  is asserted. This allows fail-safe system cooling. If this bit is 0, the fans run at their current settings and are not affected by  $\overline{\text{THERM}}$  events. If the fans are not already running when  $\overline{\text{THERM}}$  is asserted, the fans do not run to full speed.

3. Select whether  $\overline{\text{THERM}}$  timer events should generate SMBALERT interrupts.

Bit 5 (F4P) of Mask Register 2 (Reg. 0x75), when set, masks out SMBALERTs when the  $\overline{\text{THERM}}$  timer limit value is exceeded. This bit should be cleared, if SMBALERTs based on  $\overline{\text{THERM}}$  events are required.

4. Select a suitable  $\overline{\text{THERM}}$  limit value.

This value determines whether an SMBALERT is generated on the first  $\overline{\text{THERM}}$  assertion, or only if a cumulative  $\overline{\text{THERM}}$  assertion time limit is exceeded. A value of 0x00 causes an SMBALERT to be generated on the first  $\overline{\text{THERM}}$  assertion.

5. Select a  $\overline{\text{THERM}}$  monitoring time.

This value specifies how often OS or BIOS level software checks the  $\overline{\text{THERM}}$  timer. For example, BIOS could read the  $\overline{\text{THERM}}$  timer once an hour to determine the cumulative  $\overline{\text{THERM}}$  assertion time. If, for example, the total  $\overline{\text{THERM}}$  assertion time is <22.76 ms in Hour 1, >182.08 ms in Hour 2, and >5.825 s in Hour 3, this can indicate that system performance is degrading significantly, because  $\overline{\text{THERM}}$  is asserting more frequently on an hourly basis.

Alternatively, OS or BIOS level software can timestamp when the system is powered on. If an SMBALERT is generated due to the  $\overline{\text{THERM}}$  timer limit being exceeded, another timestamp can be taken. The difference in time

can be calculated for a fixed  $\overline{\text{THERM}}$  timer limit time. For example, if it takes one week for a  $\overline{\text{THERM}}$  timer limit of 2.914 s to be exceeded and the next time it takes only 1 hour, then this is an indication of a serious degradation in system performance.

### Configuring the $\overline{\text{THERM}}$ Pin as an Output

In addition to monitoring  $\overline{\text{THERM}}$  as an input, the ADT7468 can optionally drive  $\overline{\text{THERM}}$  low as an output. In cases where PROCHOT is bidirectional,  $\overline{\text{THERM}}$  can be used to throttle the processor by asserting PROCHOT. The user can preprogram system-critical thermal limits. If the temperature exceeds a thermal limit by 0.25°C,  $\overline{\text{THERM}}$  asserts low. If the temperature is still above the thermal limit on the next monitoring cycle,  $\overline{\text{THERM}}$  stays low.  $\overline{\text{THERM}}$  remains asserted low until the temperature is equal to or below the thermal limit. Because the temperature for that channel is measured only once for every monitoring cycle, after  $\overline{\text{THERM}}$  asserts it is guaranteed to remain low for at least one monitoring cycle.

The  $\overline{\text{THERM}}$  pin can be configured to assert low, if the Remote 1, local, or Remote 2  $\overline{\text{THERM}}$  temperature limits are exceeded by 0.25°C. The  $\overline{\text{THERM}}$  temperature limit registers are at Registers 0x6A, 0x6B, and 0x6C, respectively. Setting Bit 3 of Registers 0x5F, 0x60, and 0x61 enables the  $\overline{\text{THERM}}$  output feature for the Remote 1, local, and Remote 2 temperature channels, respectively. Figure 33 shows how the  $\overline{\text{THERM}}$  pin asserts low as an output in the event of a critical overtemperature.

Figure 33. Asserting  $\overline{\text{THERM}}$  as an Output, Based on Tripping  $\overline{\text{THERM}}$  Limits

An alternative method of disabling  $\overline{\text{THERM}}$  is to program the  $\overline{\text{THERM}}$  temperature limit to -64°C or less in Offset 64 mode, or -128°C or less in twos complement mode; that is, for  $\overline{\text{THERM}}$  temperature limit values less than -63°C or -128°C, respectively,  $\overline{\text{THERM}}$  is disabled.

## FAN DRIVE USING PWM CONTROL

The ADT7468 uses pulse-width modulation (PWM) to control fan speed. This relies on varying the duty cycle (or on/off ratio) of a square wave applied to the fan to vary the fan speed. The external circuitry required to drive a fan using PWM control is extremely simple. For 4-wire fans, the PWM drive might need only a pull-up resistor. In many cases, the 4-wire fan PWM input has a built-in pull-up resistor.

The ADT7468 PWM frequency can be set to a selection of low frequencies or a single high PWM frequency. The low frequency options are usually used for 2-wire and 3-wire fans, while the high frequency option is usually used with 4-wire fans.

For 2-wire or 3-wire fans, a single N-channel MOSFET is the only drive device required. The specifications of the MOSFET depend on the maximum current required by the fan being driven and the input capacitance of the FET. Because a 10 k $\Omega$  (or greater) resistor must be used as a PWM pull-up, an FET with large input capacitance can cause the PWM output to become distorted and adversely affect the fan control range. This is a requirement only when using high frequency PWM mode.

Typical notebook fans draw a nominal 170 mA, and so SOT devices can be used where board space is a concern. In desktops, fans can typically draw 250 mA to 300 mA each. If you drive several fans in parallel from a single PWM output or drive larger server fans, the MOSFET must handle the higher current requirements. The only other stipulation is that the MOSFET should have a gate voltage drive,  $V_{GS} < 3.3$  V, for direct interfacing to the PWM\_OUT pin.  $V_{GS}$  can be greater than 3.3 V as long as the pull-up on the gate is tied to 5 V. The MOSFET should also have a low on resistance to ensure that there is not significant voltage drop across the FET, which would reduce the voltage applied across the fan and, therefore, the maximum operating speed of the fan.

Figure 34 shows how to drive a 3-wire fan using PWM control.

Figure 34. Driving a 3-Wire Fan Using an N-Channel MOSFET

Figure 34 uses a 10 k $\Omega$  pull-up resistor for the TACH signal. This assumes that the TACH signal is an open-collector from the fan. In all cases, the TACH signal from the fan must be kept below 5 V maximum to prevent damaging the ADT7468. If in doubt as to whether the fan used has an open-collector or totem-pole TACH output, use one of the input signal conditioning circuits shown in the Fan Speed Measurement section.

Figure 35 shows a fan drive circuit using an NPN transistor such as a general-purpose MMBT2222. While these devices are inexpensive, they tend to have much lower current handling capabilities and higher on resistance than MOSFETs. When choosing a transistor, care should be taken to ensure that it meets the fan's current requirements. Ensure that the base resistor is chosen such that the transistor is saturated when the fan is powered on.

Because 4-wire fans are powered continuously, the fan speed is not switched on or off as with previous PWM driven/powered fans. This enables it to perform better than 3-wire fans, especially for high frequency applications.

Figure 35. Driving a 3-Wire Fan Using an NPN Transistor

Figure 36 shows a typical drive circuit for 4-wire fans.

Figure 36. Driving a 4-Wire Fan

## Driving Two Fans from PWM3

The ADT7468 has four TACH inputs available for fan speed measurement, but only three PWM drive outputs. If a fourth fan is being used in the system, it should be driven from the PWM3 output in parallel with the third fan. Figure 37 shows how to drive two fans in parallel using low cost NPN transistors. Figure 38 shows the equivalent circuit using a MOSFET.

Because the MOSFET can handle up to 3.5 A, it is simply a matter of connecting another fan directly in parallel with the first. Care should be taken in designing drive circuits with transistors and FETs to ensure that the PWM pins are not required to source current and that they sink less than the 5 mA maximum current specified on the data sheet.

## Driving up to Three Fans from PWM3

TACH measurements for fans are synchronized to particular PWM channels; for example, TACH1 is synchronized to PWM1. TACH3 and TACH4 are both synchronized to PWM3, so PWM3 can drive two fans. Alternatively, PWM3 can be programmed to synchronize TACH2, TACH3, and TACH4 to the PWM3 output. This allows PWM3 to drive two or three fans. In this case, the drive circuitry looks the same, as shown in Figure 37 and Figure 38. The SYNC bit in Register 0x62 enables this function.

Synchronization is not required in high frequency mode when used with 4-wire fans.

### <4> (SYNC) Enhance Acoustics Register 1 (Reg. 0x62)

SYNC = 1, synchronizes TACH2, TACH3, and TACH4 to PWM3.

Figure 37. Interfacing Two Fans in Parallel to the PWM3 Output Using Low Cost NPN Transistors

Figure 38. Interfacing Two Fans in Parallel to the PWM3 Output Using a Single N-Channel MOSFET

## Driving 2-Wire Fans

The ADT7468 can support 2-wire fans only when low frequency PWM mode is selected in Configuration Register 5, Bit 2. If this bit is not set to 1, the ADT7468 cannot measure the speed of 2-wire fans.

Figure 39 shows how a 2-wire fan can be connected to the ADT7468. This circuit allows the speed of a 2-wire fan to be measured, even though the fan has no dedicated TACH signal. A series resistor,  $R_{SENSE}$ , in the fan circuit converts the fan commutation pulses into a voltage, which is ac-coupled into the ADT7468 through the  $0.01\ \mu\text{F}$  capacitor. On-chip signal conditioning allows accurate monitoring of fan speed. The value of  $R_{SENSE}$  chosen depends upon the programmed input threshold and the current drawn by the fan. For fans drawing approximately 200 mA, a  $2\ \Omega$   $R_{SENSE}$  value is suitable when the threshold is programmed as 40 mV.

Figure 39. Driving a 2-Wire Fan

Figure 40 shows a typical plot of the sensing waveform at the TACH/AIN pin.

Figure 40. Fan Speed Sensing Waveform at TACH/AIN Pin

For fans that draw more current, such as larger desktop or server fans,  $R_{SENSE}$  can be reduced for the same programmed threshold. The smaller the threshold programmed the better, because more voltage is developed across the fan and the fan spins faster. Note that when the voltage spikes (either negative going or positive going) are more than 40 mV in amplitude, the fan speed can be reliably determined.

## LAYING OUT 2-WIRE AND 3-WIRE FANS

Figure 41 shows how to lay out a common circuit arrangement for 2-wire and 3-wire fans. Some components are not populated, depending on whether a 2-wire or 3-wire fan is used.

Figure 41. Planning for 2-Wire or 3-Wire Fans on a PCB

## TACH Inputs

Pins 9, 11, 12, and 14 (when configured as TACH inputs) are open-drain TACH inputs intended for fan speed measurement.

Signal conditioning in the ADT7468 accommodates the slow rise and fall times typical of fan tachometer outputs. The maximum input signal range is 0 V to 5 V, even when  $V_{CC}$  is less than 5 V. In the event that these inputs are supplied from fan outputs that exceed 0 V to 5 V, either resistive attenuation of the fan signal or diode clamping must be included to keep inputs within an acceptable range.

Figure 42 to Figure 45 show circuits for most common fan TACH outputs.

If the fan TACH output has a resistive pull-up to  $V_{CC}$ , it can be connected directly to the fan input, as shown in Figure 42.

Figure 42. Fan with TACH Pull-Up to  $V_{CC}$

If the fan output has a resistive pull-up to 12 V (or other voltage greater than 5 V) then the fan output can be clamped with a Zener diode, as shown in Figure 43. The Zener diode voltage should be chosen so that it is greater than  $V_{IH}$  of the TACH input but less than 5 V, allowing for the voltage tolerance of the Zener. A value of between 3 V and 5 V is suitable.

Figure 43. Fan with TACH Pull-Up to Voltage > 5 V, for example, 12 V  
Clamped with Zener Diode

If the fan has a strong pull-up (less than 1 kΩ) to 12 V or a totem-pole output, then a series resistor can be added to limit the Zener current, as shown in Figure 44.

Figure 44. Fan with Strong TACH Pull-Up to >  $V_{CC}$  or Totem-Pole Output,  
Clamped with Zener and Resistor

Alternatively, a resistive attenuator can be used, as shown in Figure 45.  $R_1$  and  $R_2$  should be chosen such that

$$2\text{ V} < V_{PULL-UP} \times R_2 / (R_{PULL-UP} + R_1 + R_2) < 5\text{ V}$$

The fan inputs have an input resistance of nominally 160 kΩ to ground, which should be taken into account when calculating resistor values.

With a pull-up voltage of 12 V and pull-up resistor less than 1 kΩ, suitable values for  $R_1$  and  $R_2$  would be 100 kΩ and 47 kΩ, respectively. This gives a high input voltage of 3.83 V.

Figure 45. Fan with Strong TACH Pull-Up to >  $V_{CC}$  or Totem-Pole Output,  
Attenuated with  $R_1/R_2$

### Fan Speed Measurement

The fan counter does not count the fan TACH output pulses directly, because the fan speed could be less than 1,000 RPM and it would take several seconds to accumulate a reasonably large and accurate count. Instead, the period of the fan revolution is measured by gating an on-chip 90 kHz oscillator into the input of a 16-bit counter for  $N$  periods of the fan TACH output (Figure 46), so the accumulated count is actually proportional to the fan tachometer period and inversely proportional to the fan speed.

$N$ , the number of pulses counted, is determined by the settings of Register 0x7B (TACH pulses per revolution register). This register contains two bits for each fan, allowing one, two (default), three, or four TACH pulses to be counted.

Figure 46. Fan Speed Measurement

### Fan Speed Measurement Registers

The fan tachometer readings are 16-bit values consisting of a 2-byte read from the ADT7468.

Reg. 0x28, TACH1 Low Byte = 0x00 default

Reg. 0x29, TACH1 High Byte = 0x00 default

Reg. 0x2A, TACH2 Low Byte = 0x00 default

Reg. 0x2B, TACH2 High Byte = 0x00 default

Reg. 0x2C, TACH3 Low Byte = 0x00 default

Reg. 0x2D, TACH3 High Byte = 0x00 default

Reg. 0x2E, TACH4 Low Byte = 0x00 default

Reg. 0x2F, TACH4 High Byte = 0x00 default

### Reading Fan Speed from the ADT7468

The measurement of fan speeds involves a 2-register read for each measurement. The low byte should be read first. This causes the high byte to be frozen until both high and low byte registers have been read, preventing erroneous TACH readings. The fan tachometer reading registers report back the number of

11.11  $\mu$ s period clocks (90 kHz oscillator) gated to the fan speed counter, from the rising edge of the first fan TACH pulse to the rising edge of the third fan TACH pulse (assuming two pulses per revolution are being counted). Because the device is essentially measuring the fan TACH period, the higher the count value, the slower the fan is actually running. A 16-bit fan tachometer reading of 0xFFFF indicates either that the fan has stalled or is running very slowly (<100 RPM).

## High Limit: > Comparison Performed

Because the actual fan TACH period is being measured, falling below a fan TACH limit by 1 sets the appropriate status bit and can be used to generate an SMBALERT.

## Fan TACH Limit Registers

The fan TACH limit registers are 16-bit values consisting of two bytes.

Reg. 0x54, TACH1 Minimum Low Byte = 0xFF default

Reg. 0x55, TACH1 Minimum High Byte = 0xFF default

Reg. 0x56, TACH2 Minimum Low Byte = 0xFF default

Reg. 0x57, TACH2 Minimum High Byte = 0xFF default

Reg. 0x58, TACH3 Minimum Low Byte = 0xFF default

Reg. 0x59, TACH3 Minimum High Byte = 0xFF default

Reg. 0x5A, TACH4 Minimum Low Byte = 0xFF default

Reg. 0x5B, TACH4 Minimum High Byte = 0xFF default

## Fan Speed Measurement Rate

The fan TACH readings are normally updated once every second.

The FAST bit (Bit 3) of Configuration Register 3 (Reg. 0x78), when set, updates the fan TACH readings every 250 ms.

If any of the fans are not being driven by a PWM channel but are powered directly from 5 V or 12 V, their associated dc bit in Configuration Register 3 should be set. This allows TACH readings to be taken on a continuous basis for fans connected directly to a dc source. For optimal results, the associated dc bit should always be set when using 4-wire fans.

## Calculating Fan Speed

Assuming a fan with a two pulses per revolution (and two pulses per revolution being measured), fan speed is calculated by

$$\text{Fan Speed (RPM)} = (90,000 \times 60) / \text{Fan TACH Reading}$$

where *Fan TACH Reading* is the 16-bit fan tachometer reading.

## Example:

TACH1 High Byte (Reg. 0x29) = 0x17

TACH1 Low Byte (Reg. 0x28) = 0xFF

What is Fan 1 speed in RPM?

*Fan 1 TACH Reading* = 0x17FF = 6143 (decimal)

$$\text{RPM} = (f \times 60) / \text{Fan 1 TACH Reading}$$

$$\text{RPM} = (90000 \times 60) / 6143$$

$$\text{Fan Speed} = 879 \text{ RPM}$$

## Fan Pulses per Revolution

Different fan models can output either 1, 2, 3, or 4 TACH pulses per revolution. Once the number of fan TACH pulses has been determined, it can be programmed into the fan pulses per revolution register (Reg. 0x7B) for each fan. Alternatively, this register can be used to determine the number of pulses per revolution output by a given fan. By plotting fan speed measurements at 100% speed with different pulses per revolution setting, the smoothest graph with the lowest ripple determines the correct pulses per revolution value.

## Fan Pulses per Revolution Register

<1:0> Fan 1 default = 2 pulses per revolution.

<3:2> Fan 2 default = 2 pulses per revolution.

<5:4> Fan 3 default = 2 pulses per revolution.

<7:6> Fan 4 default = 2 pulses per revolution.

00 = 1 pulse per revolution.

01 = 2 pulses per revolution.

10 = 3 pulses per revolution.

11 = 4 pulses per revolution.

### 2-Wire Fan Speed Measurements (Low Frequency Mode Only)

The ADT7468 is capable of measuring the speed of 2-wire fans, that is, fans without TACH outputs. To do this, the fan must be interfaced as shown in the Driving 2-Wire Fans section. In this case, the TACH inputs should be reprogrammed as analog inputs, AIN.

#### Configuration Register 2 (Reg. 0x73)

**Bit 3 (AIN4) = 1**, Pin 14 is reconfigured to measure the speed of a 2-wire fan using an external sensing resistor and coupling capacitor.

**Bit 2 (AIN3) = 1**, Pin 9 is reconfigured to measure the speed of a 2-wire fan using an external sensing resistor and coupling capacitor.

**Bit 1 (AIN2) = 1**, Pin 12 is reconfigured to measure the speed of a 2-wire fan using an external sensing resistor and coupling capacitor.

**Bit 0 (AIN1) = 1**, Pin 11 is reconfigured to measure the speed of a 2-wire fan using an external sensing resistor and coupling capacitor.

#### AIN Switching Threshold

Having configured the TACH inputs as AIN inputs for 2-wire measurements, a user can select the sensing threshold for the AIN signal.

#### Configuration Register 4 (Reg. 0x7D)

**<3:2> AINL**, input threshold for 2-wire fan speed measurements.

00 =  $\pm 20$  mV

01 =  $\pm 40$  mV

10 =  $\pm 80$  mV

11 =  $\pm 130$  mV

#### Fan Spin-Up

The ADT7468 has a unique fan spin-up function. It spins the fan at 100% PWM duty cycle until two TACH pulses are detected on the TACH input. Once two TACH pulses have been detected, the PWM duty cycle goes to the expected running value, for example, 33%. The advantage is that fans have different spin-up characteristics and take different times to overcome inertia. The ADT7468 runs the fans just fast enough to overcome inertia and is quieter on spin-up than fans programmed to spin up for a given spin-up time.

#### Fan Startup Timeout

To prevent the generation of false interrupts as a fan spins up (because it is below running speed), the ADT7468 includes a fan startup timeout function. During this time, the ADT7468 looks for two TACH pulses. If two TACH pulses are not detected, then an interrupt is generated.

Using Configuration Register 4 (0x40) Bit 5 (FSPDIS), this functionality can be changed (see the Disabling Fan Startup Timeout section).

#### PWM1 Configuration (Reg. 0x5C)

**<2:0> SPIN**, startup timeout for PWM1.

000 = No startup timeout

001 = 100 ms

010 = 250 ms default

011 = 400 ms

100 = 667 ms

101 = 1 s

110 = 2 s

111 = 4 s

#### PWM2 Configuration (Reg. 0x5D)

**<2:0> SPIN**, startup timeout for PWM2.

000 = No startup timeout

001 = 100 ms

010 = 250 ms default

011 = 400 ms

100 = 667 ms

101 = 1 s

110 = 2 s

111 = 4 s

#### PWM3 Configuration (Reg. 0x5E)

**<2:0> SPIN**, start-up timeout for PWM3.

000 = No startup timeout

001 = 100 ms

010 = 250 ms default

011 = 400 ms

100 = 667 ms

101 = 1 s

110 = 2 s

111 = 4 s

#### Disabling Fan Startup Timeout

Although fan startup makes fan spin-ups much quieter than fixed-time spin-ups, the option exists to use fixed spin-up times. Setting Bit 5 (FSPDIS) to 1 in Configuration Register 1 (Reg. 0x40) disables the spin-up for two TACH pulses. Instead, the fan spins up for the fixed time as selected in Reg. 0x5C to Reg. 0x5E.

## PWM Logic State

The PWM outputs can be programmed high for 100% duty cycle (noninverted) or low for 100% duty cycle (inverted).

### PWM1 Configuration (Reg. 0x5C)

<4> INV.

0 = Logic high for 100% PWM duty cycle.

1 = Logic low for 100% PWM duty cycle.

### PWM2 Configuration (Reg. 0x5D)

<4> INV.

0 = Logic high for 100% PWM duty cycle.

1 = Logic low for 100% PWM duty cycle.

### PWM3 Configuration (Reg. 0x5E)

<4> INV.

0 = Logic high for 100% PWM duty cycle.

1 = Logic low for 100% PWM duty cycle.

## Low Frequency Mode PWM Drive Frequency

The PWM drive frequency can be adjusted for the application. Register 0x5F to Register 0x61 configure the PWM frequency for PWM1 to PWM3, respectively. In high frequency mode, the PWM drive frequency is always 22.5 kHz and cannot be changed.

### PWM1 Frequency Registers (Reg. 0x5F to Reg. 0x61)

<2:0> FREQ.

000 = 11.0 Hz

001 = 14.7 Hz

010 = 22.1 Hz

011 = 29.4 Hz

100 = 35.3 Hz default

101 = 44.1 Hz

110 = 58.8 Hz

111 = 88.2 Hz

## Fan Speed Control

The ADT7468 controls fan speed using two modes: automatic and manual.

In automatic fan speed control mode, fan speed is automatically varied with temperature and without CPU intervention, once initial parameters are set up. The advantage is that, if the system hangs, the user is guaranteed that the system is protected from overheating. The automatic fan speed control incorporates a feature called dynamic  $T_{MIN}$  calibration. This feature reduces the design effort required to program the automatic fan speed control loop. See the Programming the Automatic Fan Speed Control Loop section.

In manual fan speed control mode, the ADT7468 allows the duty cycle of any PWM output to be manually adjusted. This can be useful, if the user wants to change fan speed in software or adjust PWM duty cycle output for test purposes. Bits <7:5> of Reg. 0x5C to Reg. 0x5E (PWM Configuration) control the behavior of each PWM output.

### PWM Configuration Register (Reg. 0x5C to Reg. 0x5E)

<7:5> BHVR.

111 = manual mode

Once under manual control, each PWM output can be manually updated by writing to Reg. 0x30 to Reg. 0x32 (PWMx current duty cycle registers).

### Programming the PWM Current Duty Cycle Registers

The PWM current duty cycle registers are 8-bit registers that allow the PWM duty cycle for each output to be set anywhere from 0% to 100% in steps of 0.39%. The value to be programmed into the  $PWM_{MIN}$  register is given by

$$Value \text{ (decimal)} = PWM_{MIN}/0.39$$

**Example 1:** For a PWM duty cycle of 50%,

$$Value \text{ (decimal)} = 50/0.39 = 128 \text{ (decimal)}$$

$$Value = 128 \text{ (decimal) or } 0x80 \text{ (hex)}$$

**Example 2:** For a PWM duty cycle of 33%,

$$Value \text{ (decimal)} = 33/0.39 = 85 \text{ (decimal)}$$

$$Value = 85 \text{ (decimal) or } 0x54 \text{ (hex)}$$

### PWM Duty Cycle Registers

Reg. 0x30 **PWM1 Duty Cycle** = 0x00 (0% default)

Reg. 0x31 **PWM2 Duty Cycle** = 0x00 (0% default)

Reg. 0x32 **PWM3 Duty Cycle** = 0x00 (0% default)

By reading the PWMx current duty cycle registers, the user can keep track of the current duty cycle on each PWM output, even when the fans are running in automatic fan speed control mode or acoustic enhancement mode. See the Programming the Automatic Fan Speed Control Loop section for details.

## OPERATING FROM 3.3 V STANDBY

The ADT7468 has been specifically designed to operate from a 3.3 V STBY supply. In computers that support S3 and S5 states, the core voltage of the processor is lowered in these states. If using the dynamic  $T_{MIN}$  mode, lowering the core voltage of the processor changes the CPU temperature and changes the dynamics of the system under dynamic  $T_{MIN}$  control. Likewise, when monitoring  $THERM$ , the  $THERM$  timer should be disabled during these states.

## Dynamic $T_{MIN}$ Control Register 1 (Reg. 0x36) <1> $V_{CCPLO} = 1$

When the power is supplied from 3.3 V STBY and the  $V_{CCP}$  voltage drops below the  $V_{CCP}$  low limit, the following occurs:

1. Status Bit 1 ( $V_{CCP}$ ) in Status Register 1 is set.
2.  $\overline{SMBALERT}$  is generated, if enabled.
3.  $\overline{THERM}$  monitoring is disabled. The  $\overline{THERM}$  timer should hold its value prior to the S3 or S5 state.
4. Dynamic  $T_{MIN}$  control is disabled. This prevents  $T_{MIN}$  from being adjusted due to an S3 or S5 state.
5. The ADT7468 is prevented from entering the shutdown state.

Once the core voltage,  $V_{CCP}$ , goes above the  $V_{CCP}$  low limit, everything is re-enabled and the system resumes normal operation.

## XNOR TREE TEST MODE

The ADT7468 includes an XNOR tree test mode. This mode is useful for in-circuit test equipment at board-level testing. By applying stimulus to the pins included in the XNOR tree, it is possible to detect opens or shorts on the system board.

The XNOR tree test is invoked by setting Bit 0 (XEN) of the XNOR tree test enable register (Reg. 0x6F).

Figure 47 shows the signals that are exercised in the XNOR tree test mode.

Figure 47. XNOR Tree Test

## POWER-ON DEFAULT

When the ADT7468 is powered up, it polls the  $V_{CCP}$  input.

If  $V_{CCP}$  stays below 0.75 V (the system CPU power rail is not powered up), then the ADT7468 assumes the functionality of the default registers after the ADT7468 is addressed via any valid SMBus transaction.

If  $V_{CCP}$  goes high (the system processor power rail is powered up), then a fail-safe timer begins to count down. If the ADT7468 is not addressed by any valid SMBus transaction before the fail-safe timeout (4.6 s) lapses, then the ADT7468 drives the fans to full speed. If the ADT7468 is addressed by a valid SMBus transaction after this point, the fans stop, and the ADT7468 assumes its default settings and begins normal operation.

If  $V_{CCP}$  goes high (the system processor power rail is powered up), then a fail-safe timer begins to count down. If the ADT7468 has been addressed by a valid SMBus transaction before the fail-safe timeout (4.6 s) lapses, then the ADT7468 operates normally, assuming the functionality of all the default registers. See the flow chart in Figure 48.

Figure 48. Power-On Flow Chart

## PROGRAMMING THE AUTOMATIC FAN SPEED CONTROL LOOP

Note: To more efficiently understand the automatic fan speed control loop, it is strongly recommended to use the ADT7468 evaluation board and software while reading this section.

This section provides the system designer with an understanding of the automatic fan control loop, and provides step-by-step guidance on effectively evaluating and selecting critical system parameters. To optimize the system characteristics, the designer needs to give some thought to system configuration, including the number of fans, where they are located, and what temperatures are being measured in the particular system.

The mechanical or thermal engineer who is tasked with the system thermal characterization should also be involved at the beginning of the process.

### AUTOMATIC FAN CONTROL OVERVIEW

The ADT7468 can automatically control the speed of fans based upon the measured temperature. This is done independently of CPU intervention once initial parameters are set up.

The ADT7468 has a local temperature sensor and two remote temperature channels that can be connected to a CPU on-chip thermal diode (available on Intel Pentium class and other CPUs). These three temperature channels can be used as the basis for automatic fan speed control to drive fans using pulse-width modulation (PWM).

Automatic fan speed control reduces acoustic noise by optimizing fan speed according to accurately measured temperature. Reducing fan speed can also decrease system

current consumption. The automatic fan speed control mode is very flexible owing to the number of programmable parameters, including  $T_{MIN}$  and  $T_{RANGE}$ . The  $T_{MIN}$  and  $T_{RANGE}$  values for a temperature channel and, therefore, for a given fan are critical, because they define the thermal characteristics of the system. The thermal validation of the system is one of the most important steps in the design process, so these values should be selected carefully.

Figure 49 gives a top-level overview of the automatic fan control circuitry on the ADT7468. From a systems-level perspective, up to three system temperatures can be monitored and used to control three PWM outputs. The three PWM outputs can be used to control up to four fans. The ADT7468 allows the speed of four fans to be monitored. Each temperature channel has a thermal calibration block, allowing the designer to individually configure the thermal characteristics of each temperature channel. For example, one can decide to run the CPU fan when CPU temperature increases above 60°C and a chassis fan when the local temperature increases above 45°C. At this stage, the designer has not assigned these thermal calibration settings to a particular fan drive (PWM) channel. The right side of Figure 49 shows controls that are fan-specific. The designer has individual control over parameters such as minimum PWM duty cycle, fan speed failure thresholds, and even ramp control of the PWM outputs. Automatic fan control, then, ultimately allows graceful fan speed changes that are less perceptible to the system user.

Figure 49. Automatic Fan Control Block Diagram

## STEP 1: HARDWARE CONFIGURATION

During system design, the motherboard sensing and control capabilities should be addressed early in the design stages. Decisions about how these capabilities are used should involve the system thermal/mechanical engineer. Ask the following questions:

1. What ADT7468 functionality will be used?
  - PWM2 or  $\overline{\text{SMBALERT}}$ ?
  - TACH4 fan speed measurement or overtemperature  $\overline{\text{THERM}}$  function?
  - 5 V voltage monitoring or overtemperature  $\overline{\text{THERM}}$  function?
  - 12 V voltage monitoring or VID5 input?

The ADT7468 offers multifunctional pins that can be reconfigured to suit different system requirements and physical layouts. These multifunction pins are software programmable.

2. How many fans will be supported in system, three or four?  
This influences the choice of whether to use the TACH4 pin or to reconfigure it for the  $\overline{\text{THERM}}$  function.

3. Is the CPU fan to be controlled using the ADT7468 or will it run at full speed 100% of the time?  
If run at 100%, this frees up a PWM output, but the system is louder.

4. Where will the ADT7468 be physically located in the system?  
This influences the assignment of the temperature measurement channels to particular system thermal zones.

For example, locating the ADT7468 close to the VRM controller circuitry allows the VRM temperature to be monitored using the local temperature channel.

Figure 50. Hardware Configuration Example

## RECOMMENDED IMPLEMENTATION 1

Configuring the ADT7468 as in Figure 51 provides the system designer with the following features:

1. Six VID inputs (VID0 to VID5) for VRM10 support.
2. Two PWM outputs for fan control of up to three fans. (The front and rear chassis fans are connected in parallel.)
3. Three TACH fan speed measurement inputs.
4.  $V_{CC}$  measured internally through Pin 4.
5. CPU core voltage measurement ( $V_{CORE}$ ).
6. 2.5 V measurement input used to monitor CPU current (connected to  $V_{COMP}$  output of ADP316x VRM controller). This is used to determine CPU power consumption.
7. 5 V measurement input.
8. VRM temperature using local temperature sensor.
9. CPU temperature measured using the Remote 1 temperature channel.
10. Ambient temperature measured through the Remote 2 temperature channel.
11. If not using VID5, this pin can be reconfigured as the 12 V monitoring input.
12. Bidirectional  $\overline{THERM}$  pin allows the monitoring of  $\overline{PROCHOT}$  output from an Intel P4 processor, for example, or can be used as an overtemperature  $\overline{THERM}$  output.
13.  $\overline{SMBALERT}$  system interrupt output.

Figure 51. Recommended Implementation 1

04499-0-056

## RECOMMENDED IMPLEMENTATION 2

Configuring the ADT7468 as in Figure 52 provides the system designer with the following features:

1. Six VID inputs (VID0 to VID5) for VRM10 support.
2. Three PWM outputs for fan control of up to three fans. (All three fans can be individually controlled.)
3. Three TACH fan speed measurement inputs.
4.  $V_{CC}$  measured internally through Pin 4.
5. CPU core voltage measurement ( $V_{CORE}$ ).
6. 2.5 V measurement input used to monitor CPU current (connected to  $V_{COMP}$  output of ADP316x VRM controller). This is used to determine CPU power consumption.
7. 5 V measurement input.
8. VRM temperature using local temperature sensor.
9. CPU temperature measured using the Remote 1 temperature channel.
10. Ambient temperature measured through the Remote 2 temperature channel.
11. If not using VID5, this pin can be reconfigured as the 12 V monitoring input.
12. Bidirectional  $\overline{THERM}$  pin allows the monitoring of  $\overline{PROCHOT}$  output from an Intel P4 processor, for example, or can be used as an overtemperature  $\overline{THERM}$  output.

Figure 52. Recommended Implementation 2

## STEP 2: CONFIGURING THE MUX

After the system hardware configuration is determined, the fans can be assigned to particular temperature channels. Not only can fans be assigned to individual channels, but the behavior of the fans is also configurable. For example, fans can be run under automatic fan control, can be run manually (under software control), or can be run at the fastest speed calculated by multiple temperature channels. The MUX is the bridge between temperature measurement channels and the three PWM outputs.

**Bits <7:5> (BHVR)** of Registers 0x5C, 0x5D, and 0x5E (PWM configuration registers) control the behavior of the fans connected to the PWM1, PWM2, and PWM3 outputs. The values selected for these bits determine how the MUX connects a temperature measurement channel to a PWM output.

### Automatic Fan Control MUX Options

<7:5> (BHVR), Registers 0x5C, 0x5D, 0x5E.

000 = Remote 1 temperature controls PWMx

001 = local temperature controls PWMx

010 = Remote 2 temperature controls PWMx

101 = Fastest speed calculated by local and Remote 2 temperature controls PWMx

110 = Fastest speed calculated by all three temperature channels controls PWMx

The Fastest Speed Calculated options pertain to controlling one PWM output based on multiple temperature channels. The thermal characteristics of the three temperature zones can be set to drive a single fan. An example would be the fan turning on when Remote 1 temperature exceeds 60°C or if the local temperature exceeds 45°C.

### Other MUX Options

<7:5> (BHVR), Registers 0x5C, 0x5D, 0x5E.

011 = PWMx runs full speed

100 = PWMx disabled (default)

111 = manual mode. PWMx is runner under software control. In this mode, PWM duty cycle registers (Registers 0x30 to 0x32) are writable and control the PWM outputs.

Figure 53. Assigning Temperature Channels to Fan Channels

### MUX Configuration Example

This is an example of how to configure the MUX in a system using the ADT7468 to control three fans. The CPU fan sink is controlled by PWM1, the front chassis fan is controlled by PWM2, and the rear chassis fan is controlled by PWM3. The MUX is configured for the following fan control behavior:

- PWM1 (CPU fan sink) is controlled by the fastest speed calculated by the local (VRM temperature) and Remote 2 (processor) temperature. In this case, the CPU fan sink is also being used to cool the VRM.
- PWM2 (front chassis fan) is controlled by the Remote 1 temperature (ambient).
- PWM3 (rear chassis fan) is controlled by the Remote 1 temperature (ambient).

### Example MUX Settings

<7:5> (BHVR), PWM1 Configuration Register 0x5C.

101 = Fastest speed calculated by local and Remote 2 temperature controls PWM1

<7:5> (BHVR), PWM2 Configuration Register 0x5D.

000 = Remote 1 temperature controls PWM2

<7:5> (BHVR), PWM3 Configuration Register 0x5E.

000 = Remote 1 temperature controls PWM3

These settings configure the MUX, as shown in Figure 54.

Figure 54. MUX Configuration Example

### STEP 3: $T_{MIN}$ SETTINGS FOR THERMAL CALIBRATION CHANNELS

$T_{MIN}$  is the temperature at which the fans start to turn on under automatic fan control. The speed at which the fan runs at  $T_{MIN}$  is programmed later. The  $T_{MIN}$  values chosen are temperature channel specific, for example, 25°C for ambient channel, 30°C for VRM temperature, and 40°C for processor temperature.

$T_{MIN}$  is an 8-bit value, either two's complement or Offset 64, that can be programmed in 1°C increments. There is a  $T_{MIN}$  register associated with each temperature measurement channel: Remote 1 Local, and Remote 2 Temp. Once the  $T_{MIN}$  value is exceeded, the fan turns on and runs at the minimum PWM duty cycle. The fan turns off once the temperature has dropped below  $T_{MIN} - T_{HYST}$ .

To overcome fan inertia, the fan is spun up until two valid TACH rising edges are counted. See the Fan Startup Timeout section for more details. In some cases, primarily for psycho-acoustic reasons, it is desirable that the fan never switch off below  $T_{MIN}$ . Bits <7:5> of Enhanced Acoustics Register 1 (Reg. 0x62), when set, keep the fans running at the PWM minimum duty cycle, if the temperature should fall below  $T_{MIN}$ .

#### $T_{MIN}$ Registers

Reg. 0x67, Remote 1 Temperature  $T_{MIN} = 0x9A$  (90°C)

Reg. 0x68, Local Temperature  $T_{MIN} = 0x9A$  (90°C)

Reg. 0x69, Remote 2 Temperature  $T_{MIN} = 0x9A$  (90°C)

#### Enhance Acoustics Register 1 (Reg. 0x62)

**Bit 7 (MIN3) = 0**, PWM3 is off (0% PWM duty cycle) when temperature is below  $T_{MIN} - T_{HYST}$ .

**Bit 7 (MIN3) = 1**, PWM3 runs at PWM3 minimum duty cycle below  $T_{MIN} - T_{HYST}$ .

**Bit 6 (MIN2) = 0**, PWM2 is off (0% PWM duty cycle) when temperature is below  $T_{MIN} - T_{HYST}$ .

**Bit 6 (MIN2) = 1**, PWM2 runs at PWM2 minimum duty cycle below  $T_{MIN} - T_{HYST}$ .

**Bit 5 (MIN1) = 0**, PWM1 is off (0% PWM duty cycle) when temperature is below  $T_{MIN} - T_{HYST}$ .

**Bit 5 (MIN1) = 1**, PWM1 runs at PWM1 minimum duty cycle below  $T_{MIN} - T_{HYST}$ .

Figure 55. Understanding the  $T_{MIN}$  Parameter

#### STEP 4: PWM<sub>MIN</sub> FOR EACH PWM (FAN) OUTPUT

PWM<sub>MIN</sub> is the minimum PWM duty cycle at which each fan in the system runs. It is also the start speed for each fan under automatic fan control once the temperature rises above T<sub>MIN</sub>. For maximum system acoustic benefit, PWM<sub>MIN</sub> should be as low as possible. Depending on the fan used, the PWM<sub>MIN</sub> setting is usually in the 20% to 33% duty cycle range. This value can be found through fan validation.

Figure 56. PWM<sub>MIN</sub> Determines Minimum PWM Duty Cycle

More than one PWM output can be controlled from a single temperature measurement channel. For example, Remote 1 temperature can control PWM1 and PWM2 outputs. If two different fans are used on PWM1 and PWM2, then the fan characteristics can be set up differently. As a result, Fan 1 driven by PWM1 can have a different PWM<sub>MIN</sub> value than that of Fan 2 connected to PWM2. Figure 57 illustrates this as PWM1<sub>MIN</sub> (front fan) is turned on at a minimum duty cycle of 20%, while PWM2<sub>MIN</sub> (rear fan) turns on at a minimum of 40% duty cycle. Note, however, that both fans turn on at exactly the same temperature, defined by T<sub>MIN</sub>.

Figure 57. Operating Two Different Fans from a Single Temperature Channel

#### Programming the PWM<sub>MIN</sub> Registers

The PWM<sub>MIN</sub> registers are 8-bit registers that allow the minimum PWM duty cycle for each output to be configured anywhere from 0% to 100%. This allows the minimum PWM duty cycle to be set in steps of 0.39%.

The value to be programmed into the PWM<sub>MIN</sub> register is given by

$$\text{Value (decimal)} = \text{PWM}_{\text{MIN}} / 0.39$$

**Example 1:** For a minimum PWM duty cycle of 50%,

$$\text{Value (decimal)} = 50 / 0.39 = 128 \text{ (decimal)}$$

$$\text{Value} = 128 \text{ (decimal) or } 80 \text{ (hex)}$$

**Example 2:** For a minimum PWM duty cycle of 33%,

$$\text{Value (decimal)} = 33 / 0.39 = 85 \text{ (decimal)}$$

$$\text{Value} = 85 \text{ (decimal) or } 54 \text{ (hex)}$$

#### PWM<sub>MIN</sub> Registers

Reg. 0x64, PWM1 Minimum Duty Cycle = 0x80 (50% default)

Reg. 0x65, PWM2 Minimum Duty Cycle = 0x80 (50% default)

Reg. 0x66, PWM3 Minimum Duty Cycle = 0x80 (50% default)

#### Note on Fan Speed and PWM Duty Cycle

The PWM duty cycle does not directly correlate to fan speed in RPM. Running a fan at 33% PWM duty cycle does not equate to running the fan at 33% speed. Driving a fan at 33% PWM duty cycle actually runs the fan at closer to 50% of its full speed. This is because fan speed in %RPM generally relates to the square root of PWM duty cycle. Given a PWM square wave as the drive signal, fan speed in RPM approximates to

$$\% \text{ fanspeed} = \sqrt{\text{PWM duty cycle} \times 10}$$

#### STEP 5: PWM<sub>MAX</sub> FOR PWM (FAN) OUTPUTS

PWM<sub>MAX</sub> is the maximum duty cycle that each fan in the system runs at under the automatic fan speed control loop. For maximum system acoustic benefit, PWM<sub>MAX</sub> should be as low as possible, but should be capable of maintaining the processor temperature limit at an acceptable level. If the THERM temperature limit is exceeded, the fans are still boosted to 100% for fail-safe cooling.

There is a PWM<sub>MAX</sub> limit for each fan channel. The default value of this register is 0xFF and so has no effect unless it is programmed.

Figure 58.  $PWM_{MAX}$  Determines Maximum PWM Duty Cycle below the  $T_{THERM}$  Temperature Limit

## Programming the $PWM_{MAX}$ Registers

The  $PWM_{MAX}$  registers are 8-bit registers that allow the maximum PWM duty cycle for each output to be configured anywhere from 0% to 100%. This allows the maximum PWM duty cycle to be set in steps of 0.39%.

The value to be programmed into the  $PWM_{MAX}$  register is given by

$$\text{Value (decimal)} = PWM_{MAX}/0.39$$

**Example 1:** For a maximum PWM duty cycle of 50%,

$$\text{Value (decimal)} = 50/0.39 = 128 \text{ (decimal)}$$

$$\text{Value} = 128 \text{ (decimal) or } 80 \text{ (hex)}$$

**Example 2:** For a minimum PWM duty cycle of 75%,

$$\text{Value (decimal)} = 75/0.39 = 85 \text{ (decimal)}$$

$$\text{Value} = 192 \text{ (decimal) or } C0 \text{ (hex)}$$

## $PWM_{MAX}$ Registers

Reg. 0x38, **PWM1 Maximum Duty Cycle** = 0xFF  
(100% default)

Reg. 0x39, **PWM2 Maximum Duty Cycle** = 0xFF  
(100% default)

Reg. 0x3A, **PWM3 Maximum Duty Cycle** = 0xFF  
(100% default)

See the Note on Fan Speed and PWM Duty Cycle on Page 43.

## STEP 6: $T_{RANGE}$ FOR TEMPERATURE CHANNELS

$T_{RANGE}$  is the range of temperature over which automatic fan control occurs once the programmed  $T_{MIN}$  temperature has been exceeded.  $T_{RANGE}$  is a temperature slope, not an arbitrary value, that is, a  $T_{RANGE}$  of 40°C holds true only for  $PWM_{MIN} = 33\%$ . If  $PWM_{MIN}$  is increased or decreased, the effective  $T_{RANGE}$  changes.

Figure 59.  $T_{RANGE}$  Parameter Affects Cooling Slope

The  $T_{RANGE}$  or fan control slope is determined by the following procedure:

1. Determine the maximum operating temperature for that channel (for example, 70°C).
2. Determine experimentally the fan speed (PWM duty cycle value) that does not exceed the temperature at the worst-case operating points. (For example, 70°C is reached when the fans are running at 50% PWM duty cycle.)
3. Determine the slope of the required control loop to meet these requirements.
4. Using the ADT7468 evaluation software, you can graphically program and visualize this functionality. Ask your local Analog Devices representative for details.

Figure 60. Adjusting  $PWM_{MIN}$  Affects  $T_{RANGE}$

$T_{\text{RANGE}}$  is implemented as a slope, which means that as  $\text{PWM}_{\text{MIN}}$  is changed,  $T_{\text{RANGE}}$  changes, but the actual slope remains the same. The higher the  $\text{PWM}_{\text{MIN}}$  value, the smaller the effective  $T_{\text{RANGE}}$ , that is, the fan reaches full speed (100%) at a lower temperature.

Figure 61. Increasing  $\text{PWM}_{\text{MIN}}$  Changes Effective  $T_{\text{RANGE}}$

For a given  $T_{\text{RANGE}}$  value, the temperature at which the fan runs at full speed for different  $\text{PWM}_{\text{MIN}}$  values can be easily calculated:

$$T_{\text{MAX}} = T_{\text{MIN}} + (\text{Max DC} - \text{Min DC}) \times T_{\text{RANGE}} / 170$$

where:

$T_{\text{MAX}}$  is the temperature at which the fan runs full speed.

$T_{\text{MIN}}$  is the temperature at which the fan turns on.

$\text{Max DC}$  is the maximum duty cycle (100%) = 255 decimal.

$\text{Min DC}$  is equal to  $\text{PWM}_{\text{MIN}}$ .

$T_{\text{RANGE}}$  is the duty PWM duty cycle vs. temperature slope.

**Example:** Calculate  $T$ , given that  $T_{\text{MIN}} = 30^\circ\text{C}$ ,  $T_{\text{RANGE}} = 40^\circ\text{C}$ , and  $\text{PWM}_{\text{MIN}} = 10\%$  duty cycle = 26 (decimal).

$$T_{\text{MAX}} = T_{\text{MIN}} + (\text{Max DC} - \text{Min DC}) \times T_{\text{RANGE}} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (100\% - 10\%) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (255 - 26) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 84^\circ\text{C} \text{ (effective } T_{\text{RANGE}} = 54^\circ\text{C)}$$

**Example:** Calculate  $T_{\text{MAX}}$ , given that  $T_{\text{MIN}} = 30^\circ\text{C}$ ,  $T_{\text{RANGE}} = 40^\circ\text{C}$ , and  $\text{PWM}_{\text{MIN}} = 25\%$  duty cycle = 64 (decimal).

$$T_{\text{MAX}} = T_{\text{MIN}} + (\text{Max DC} - \text{Min DC}) \times T_{\text{RANGE}} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (100\% - 25\%) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (255 - 64) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 75^\circ\text{C} \text{ (effective } T_{\text{RANGE}} = 45^\circ\text{C)}$$

**Example:** Calculate  $T_{\text{MAX}}$ , given that  $T_{\text{MIN}} = 30^\circ\text{C}$ ,  $T_{\text{RANGE}} = 40^\circ\text{C}$ , and  $\text{PWM}_{\text{MIN}} = 33\%$  duty cycle = 85 (decimal).

$$T_{\text{MAX}} = T_{\text{MIN}} + (\text{Max DC} - \text{Min DC}) \times T_{\text{RANGE}} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (100\% - 33\%) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (255 - 85) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 70^\circ\text{C} \text{ (effective } T_{\text{RANGE}} = 40^\circ\text{C)}$$

**Example:** Calculate  $T_{\text{MAX}}$ , given that  $T_{\text{MIN}} = 30^\circ\text{C}$ ,  $T_{\text{RANGE}} = 40^\circ\text{C}$ , and  $\text{PWM}_{\text{MIN}} = 50\%$  duty cycle = 128 (decimal).

$$T_{\text{MAX}} = T_{\text{MIN}} + (\text{Max DC} - \text{Min DC}) \times T_{\text{RANGE}} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (100\% - 50\%) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 30^\circ\text{C} + (255 - 128) \times 40^\circ\text{C} / 170$$

$$T_{\text{MAX}} = 60^\circ\text{C} \text{ (effective } T_{\text{RANGE}} = 30^\circ\text{C)}$$

### Selecting a $T_{\text{RANGE}}$ Slope

The  $T_{\text{RANGE}}$  value can be selected for each temperature channel: Remote 1, local, and Remote 2 temperature. Bits <7:4> ( $T_{\text{RANGE}}$ ) of Registers 0x5F to 0x61 define the  $T_{\text{RANGE}}$  value for each temperature channel.

Table 13. Selecting a  $T_{\text{RANGE}}$  Value

| Bits <7:4> <sup>1</sup> | $T_{\text{RANGE}}$ (°C) |
|-------------------------|-------------------------|
| 0000                    | 2                       |
| 0001                    | 2.5                     |
| 0010                    | 3.33                    |
| 0011                    | 4                       |
| 0100                    | 5                       |
| 0101                    | 6.67                    |
| 0110                    | 8                       |
| 0111                    | 10                      |
| 1000                    | 13.33                   |
| 1001                    | 16                      |
| 1010                    | 20                      |
| 1011                    | 26.67                   |
| 1100                    | 32 (default)            |
| 1101                    | 40                      |
| 1110                    | 53.33                   |
| 1111                    | 80                      |

<sup>1</sup> Register 0x5F configures Remote 1  $T_{\text{RANGE}}$ .

Register 0x60 configures Local  $T_{\text{RANGE}}$ .

Register 0x61 configures Remote 2  $T_{\text{RANGE}}$ .

### Summary of $T_{\text{RANGE}}$ Function

When using the automatic fan control function, the temperature at which the fan reaches full speed can be calculated by

$$T_{\text{MAX}} = T_{\text{MIN}} + T_{\text{RANGE}} \quad (1)$$

Equation 1 holds true only when  $\text{PWM}_{\text{MIN}}$  is equal to 33% PWM duty cycle.

Increasing or decreasing PWM<sub>MIN</sub> changes the effective T<sub>RANGE</sub>, although the fan control still follows the same PWM duty cycle to temperature slope. The effective T<sub>RANGE</sub> for different PWM<sub>MIN</sub> values can be calculated using Equation 2:

$$T_{MAX} = T_{MIN} + (Max\ DC - Min\ DC) \times T_{RANGE}/170 \quad (2)$$

where:

$(Max\ DC - Min\ DC) \times T_{RANGE}/170$  is the effective T<sub>RANGE</sub> value.

See the Note on Fan Speed and PWM Duty Cycle.

Figure 62 shows PWM duty cycle versus temperature for each T<sub>RANGE</sub> setting. The lower graph shows how each T<sub>RANGE</sub> setting affects fan speed versus temperature. As can be seen from the graph, the effect on fan speed is nonlinear.

Figure 62. T<sub>RANGE</sub> Vs. Actual Fan Speed Profile

The graphs in Figure 62 assume that the fan starts from 0% PWM duty cycle. Clearly, the minimum PWM duty cycle, PWM<sub>MIN</sub>, needs to be factored in to see how the loop actually performs in the system. Figure 63 shows how T<sub>RANGE</sub> is affected when the PWM<sub>MIN</sub> value is set to 20%. It can be seen that the fan actually runs at about 45% fan speed when the temperature exceeds T<sub>MIN</sub>.

Figure 63. T<sub>RANGE</sub> and % Fan Speed Slopes with PWM<sub>MIN</sub> = 20%

## Example: Determining T<sub>RANGE</sub> for Each Temperature Channel

The following example shows how the different T<sub>MIN</sub> and T<sub>RANGE</sub> settings can be applied to three different thermal zones. In this example, the following T<sub>RANGE</sub> values apply:

T<sub>RANGE</sub> = 80°C for ambient temperature

T<sub>RANGE</sub> = 53.3°C for CPU temperature

T<sub>RANGE</sub> = 40°C for VRM temperature

This example uses the MUX configuration described in Step 2, with the ADT7468 connected as shown in Figure 54. Both CPU temperature and VRM temperature drive the CPU fan connected to PWM1. Ambient temperature drives the front chassis fan and rear chassis fan connected to PWM2 and PWM3. The front chassis fan is configured to run at PWM<sub>MIN</sub> = 20%. The rear chassis fan is configured to run at PWM<sub>MIN</sub> = 30%. The CPU fan is configured to run at PWM<sub>MIN</sub> = 10%.

## Note on 4-Wire Fans

The control range for 4-wire fans is much wider than that of 2-wire or 3-wire fans. In many cases, 4-wire fans can start with a PWM drive of as little as 20%.

Figure 64.  $T_{\text{RANGE}}$  and % Fan Speed Slopes for VRM, Ambient, and CPU Temperature Channels

## STEP 7: $T_{\text{THERM}}$ FOR TEMPERATURE CHANNELS

$T_{\text{THERM}}$  is the absolute maximum temperature allowed on a temperature channel. Above this temperature, a component such as the CPU or VRM might be operating beyond its safe operating limit. When the temperature measured exceeds  $T_{\text{THERM}}$ , all fans are driven at 100% PWM duty cycle (full speed) to provide critical system cooling.

The fans remain running at 100% until the temperature drops below  $T_{\text{THERM}}$  minus *hysteresis*, where *hysteresis* is the number programmed into the Hysteresis Registers 0x6D and 0x6E. The default hysteresis value is 4°C.

The  $T_{\text{THERM}}$  limit should be considered the maximum worst-case operating temperature of the system. Because exceeding any  $T_{\text{THERM}}$  limit runs all fans at 100%, it has very negative acoustic effects. Ultimately, this limit should be set up as a fail-safe, and one should ensure that it is not exceeded under normal system operating conditions.

Note that the  $T_{\text{THERM}}$  limits are nonmaskable and affect the fan speed no matter how automatic fan control settings are configured. This allows some flexibility, because a  $T_{\text{RANGE}}$  value can be selected based on its slope, while a hard limit (such as 70°C), can be programmed as  $T_{\text{MAX}}$  (the temperature at which the fan reaches full speed) by setting  $T_{\text{THERM}}$  to that limit (for example, 70°C).

### **THERM Registers**

Reg. 0x6A, **Remote 1  $T_{\text{THERM}}$  limit** = 0xA4 (100°C default)

Reg. 0x6B, **Local  $T_{\text{THERM}}$  limit** = 0xA4 (100°C default)

Reg. 0x6C, **Remote 2  $T_{\text{THERM}}$  limit** = 0xA4 (100°C default)

### **Hysteresis Registers**

Reg. 0x6D, **Remote 1, Local Hysteresis Register**

<7:4>, Remote 1 temperature hysteresis (4°C default).

<3:0>, Local temperature hysteresis (4°C default).

Reg. 0x6E, **Remote 2 Temperature Hysteresis Register**

<7:4>, Remote 2 temperature hysteresis (4°C default).

Because each hysteresis setting is four bits, hysteresis values are programmable from 1°C to 15°C. It is not recommended that hysteresis values ever be programmed to 0°C, because this disables hysteresis. In effect, this would cause the fans to cycle between normal speed and 100% speed, creating unsettling acoustic noise.

Figure 65. How  $T_{THERM}$  Relates to Automatic Fan Control

## STEP 8: $T_{HYST}$ FOR TEMPERATURE CHANNELS

$T_{HYST}$  is the amount of extra cooling a fan provides after the temperature measured has dropped back below  $T_{MIN}$  before the fan turns off. The premise for temperature hysteresis ( $T_{HYST}$ ) is that, without it, the fan would merely chatter or cycle on and off regularly whenever temperature is hovering at about the  $T_{MIN}$  setting.

The  $T_{HYST}$  value chosen determines the amount of time needed for the system to cool down or heat up as the fan is turning on and off. Values of hysteresis are programmable in the range 1°C to 15°C. Larger values of  $T_{HYST}$  prevent the fans from chattering on and off. The  $T_{HYST}$  default value is set at 4°C.

The  $T_{HYST}$  setting applies not only to the temperature hysteresis for fan on/off, but the same setting is used for the  $T_{THERM}$  hysteresis value, described in Step 6. Therefore, programming Registers 0x6D and 0x6E sets the hysteresis for both fan on/off and the  $T_{THERM}$  function.

## Hysteresis Registers

Reg. 0x6D, Remote 1, Local Hysteresis Register

<7:4>, Remote 1 temperature hysteresis (4°C default).

<3:0>, local temperature hysteresis (4°C default).

Reg. 0x6E, Remote 2 Temp Hysteresis Register

<7:4>, Remote 2 temperature hysteresis (4°C default).

In some applications, it is required that fans not turn off below  $T_{MIN}$ , but remain running at  $PWM_{MIN}$ . Bits <7:5> of Enhanced Acoustics Register 1 (Reg. 0x62) allow the fans to be turned off or to be kept spinning below  $T_{MIN}$ . If the fans are always on, the  $T_{HYST}$  value has no effect on the fan when the temperature drops below  $T_{MIN}$ .

Figure 66. The  $T_{HYST}$  Value Applies to Fan On/Off Hysteresis and  $\overline{THERM}$  Hysteresis

#### Enhance Acoustics Register 1 (Reg. 0x62)

**Bit 7 (MIN3) = 0**, PWM3 is off (0% PWM duty cycle) when temperature is below  $T_{MIN} - T_{HYST}$ .

**Bit 7 (MIN3) = 1**, PWM3 runs at PWM3 minimum duty cycle below  $T_{MIN} - T_{HYST}$ .

**Bit 6 (MIN2) = 0**, PWM2 is off (0% PWM duty cycle) when temperature is below  $T_{MIN} - T_{HYST}$ .

**Bit 6 (MIN2) = 1**, PWM2 runs at PWM2 minimum duty cycle below  $T_{MIN} - T_{HYST}$ .

**Bit 5 (MIN1) = 0**, PWM1 is off (0% PWM duty cycle) when temperature is below  $T_{MIN} - T_{HYST}$ .

**Bit 5 (MIN1) = 1**, PWM1 runs at PWM1 minimum duty cycle below  $T_{MIN} - T_{HYST}$ .

#### DYNAMIC $T_{MIN}$ CONTROL MODE

In addition to the automatic fan speed control mode described in the Automatic Fan Control Overview section, the ADT7468 has a mode that extends the basic automatic fan speed control loop. Dynamic  $T_{MIN}$  control allows the ADT7468 to intelligently adapt the system's cooling solution for best system performance or lowest possible system acoustics, depending on user or design requirements. Use of dynamic  $T_{MIN}$  control alleviates the need to design for worst-case conditions and significantly reduces system design and validation time.

#### Designing for Worst-Case Conditions

System design must always allow for worst-case conditions. In PC design, the worst-case conditions include, but are not limited to the following:

- Worst-Case Altitude**

A computer can be operated at different altitudes. The altitude affects the relative air density, which alters the effectiveness of the fan cooling solution. For example, comparing 40°C air temperature at 10,000 ft. to 20°C air temperature at sea level, relative air density is increased by 40%. This means that the fan can spin 40% slower and make less noise at sea level than at 10,000 ft. while keeping the system at the same temperature at both locations.

- Worst-Case Fan**

Due to manufacturing tolerances, fan speeds in RPM are normally quoted with a tolerance of  $\pm 20\%$ . The designer needs to assume that the fan RPM can be 20% below tolerance. This translates to reduced system airflow and elevated system temperature. Note that fans 20% out of tolerance can negatively impact system acoustics, because they run faster and generate more noise.

- Worst-Case Chassis Airflow**

The same motherboard can be used in a number of different chassis configurations. The design of the chassis and the physical location of fans and components determine the system thermal characteristics. Moreover, for a given chassis, the addition of add-in cards, cables, or other system configuration options can alter the system airflow and reduce the effectiveness of the system cooling solution. The cooling solution can also be inadvertently altered by the end user. (For example, placing a computer against a wall can block the air ducts and reduce system airflow.)

Figure 67. Chassis Airflow Issues

- Worst-Case Processor Power Consumption**

This data sheet maximum does not necessarily reflect the true processor power consumption. Designing for worst-case CPU power consumption can result in a processor becoming overcooled (generating excess system noise).

- Worst-Case Peripheral Power Consumption**

The tendency is to design to data sheet maximums for peripheral components (again overcooling the system).

- Worst-Case Assembly**

Every system manufactured is unique because of manufacturing variations. Heat sinks may be loose fitting or slightly misaligned. Too much or too little thermal grease might be used, or variations in application pressure for thermal interface material could affect the efficiency of the thermal solution. Accounting for manufacturing variations in every system is difficult; therefore, the system must be designed for the worst case.

Figure 68. Thermal Model

Although a design usually accounts for worst-case conditions in all these cases, the actual system is almost never operated at worst-case conditions. The alternative to designing for the worst case is to use the dynamic  $T_{MIN}$  control function.

### Dynamic $T_{MIN}$ Control Overview

Dynamic  $T_{MIN}$  control mode builds upon the basic automatic fan control loop by adjusting the  $T_{MIN}$  value based on system performance and measured temperature. This is important, because, instead of designing for the worst case, the system thermals can be defined as operating zones. ADT7468 can self-adjust its fan control loop to maintain either an operating zone temperature or a system target temperature. For example, one can specify that the ambient temperature in a system should be maintained at 50°C. If the temperature is below 50°C, the fans might not need to run or might run very slowly. If the temperature is higher than 50°C, the fans need to throttle up.

The challenge presented by any thermal design is finding the right settings to suit the system's fan control solution. This can involve designing for the worst case, followed by weeks of system thermal characterization, and finally fan acoustic optimization (for psycho-acoustic reasons). Getting the most benefit from the automatic fan control mode involves characterizing the system to find the best  $T_{MIN}$  and  $T_{RANGE}$  settings for the control loop, and the best PWM $_{MIN}$  value for the quietest fan speed setting. Using the ADT7468's dynamic  $T_{MIN}$  control mode, however, shortens the characterization time and alleviates tweaking the control loop settings, because the device can self-adjust during system operation.

Dynamic  $T_{MIN}$  control mode is operated by specifying the operating zone temperatures required for the system. Associated with this control mode are three operating point registers, one

for each temperature channel. This allows the system thermal solution to be broken down into distinct thermal zones. For example, CPU operating temperature is 70°C, VRM operating temperature is 80°C, and ambient operating temperature is 50°C. The ADT7468 dynamically alters the control solution to maintain each zone temperature as closely as possible to its target operating point.

#### Operating Point Registers

Reg. 0x33, **Remote 1 Operating Point** = 0xA4 (100°C default)

Reg. 0x34, **Local Operating Point** = 0xA4 (100°C default)

Reg. 0x35, **Remote 2 Operating Point** = 0xA4 (100°C default)

Figure 69 shows an overview of the parameters that affect the operation of the dynamic  $T_{MIN}$  control loop.

Figure 69. Dynamic  $T_{MIN}$  Control Loop

Table 14 provides a brief description of each parameter.

**Table 14.  $T_{MIN}$  Control Loop Parameters**

| Parameter       | Description                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $T_{LOW}$       | If the temperature drops below the $T_{LOW}$ limit, an error flag is set in a status register and an $SMBALERT$ interrupt can be generated.                                                          |
| $T_{HIGH}$      | If the temperature exceeds the $T_{HIGH}$ limit, an error flag is set in a status register and an $SMBALERT$ interrupt can be generated.                                                             |
| $T_{MIN}$       | The temperature at which the fan turns on under automatic fan speed control.                                                                                                                         |
| Operating point | The target temperature for a particular temperature zone. The ADT7468 attempts to maintain system temperature at about the operating point by adjusting the $T_{MIN}$ parameter of the control loop. |
| $T_{THERM}$     | If the temperature exceeds this critical limit, the fans can be run at 100% for maximum cooling.                                                                                                     |
| $T_{RANGE}$     | Programs the PWM duty cycle vs. temperature control slope.                                                                                                                                           |

#### Dynamic $T_{MIN}$ Control Programming

Because the dynamic  $T_{MIN}$  control mode is a basic extension of the automatic fan control mode, program the automatic fan control mode parameters first, as described in Step 1 to Step 8, then proceed with dynamic  $T_{MIN}$  control mode programming.

#### STEP 9: OPERATING POINTS FOR TEMPERATURE CHANNELS

The operating point for each temperature channel is the optimal temperature for that thermal zone. The hotter each zone is allowed to be, the quieter the system, because the fans are not required to run as fast. The ADT7468 increases or decreases fan speeds as necessary to maintain the operating point temperature, allowing for system-to-system variation and removing the need for worst-case design. If a sensible operating point value is chosen, any  $T_{MIN}$  value can be selected in the system characterization. If the  $T_{MIN}$  value is too low, the fans run sooner than required, and the temperature is below the operating point. In response, the ADT7468 increases  $T_{MIN}$  to keep the fans off longer and to allow the temperature zone to get closer to the operating point. Likewise, too high a  $T_{MIN}$  value causes the operating point to be exceeded, and in turn, the ADT7468 reduces  $T_{MIN}$  to turn the fans on sooner to cool the system.

#### Programming Operating Point Registers

There are three operating point registers, one for each temperature channel. These 8-bit registers allow the operating point temperatures to be programmed with 1°C resolution.

#### Operating Point Registers

Reg. 0x33, **Remote 1 Operating Point** = 0xA4 (100°C default)

Reg. 0x34, **Local Operating Point** = 0xA4 (100°C default)

Reg. 0x35, **Remote 2 Operating Point** = 0xA4 (100°C default)

Figure 70. Operating Point Value Dynamically Adjusts Automatic Fan Control Settings

## STEP 10: HIGH AND LOW LIMITS FOR TEMPERATURE CHANNELS

The low limit defines the temperature at which the  $T_{MIN}$  value starts to be increased, if temperature falls below this value. This has the net effect of reducing the fan speed, allowing the system to get hotter. An interrupt can be generated when the temperature drops below the low limit.

The high limit defines the temperature at which the  $T_{MIN}$  value starts to be reduced, if temperature increases above this value. This has the net effect of increasing fan speed to cool down the system. An interrupt can be generated when the temperature rises above the high limit.

### Programming High and Low Limits

There are six limit registers; a high limit and low limit are associated with each temperature channel. These 8-bit registers allow the high and low limit temperatures to be programmed with 1°C resolution.

### Temperature Limit Registers

Reg. 0x4E, Remote 1 Temperature Low Limit = 0x01

Reg. 0x4F, Remote 1 Temperature High Limit = 0x7F

Reg. 0x50, Local Temperature Low Limit = 0x01

Reg. 0x51, Local Temperature High Limit = 0x7F

Reg. 0x52, Remote 2 Temperature Low Limit = 0x01

Reg. 0x53, Remote 2 Temperature High Limit = 0x7F

## How Dynamic $T_{MIN}$ Control Works

The basic premise is as follows:

1. Set the target temperature for the temperature zone, which could be, for example, the Remote 1 thermal diode. This value is programmed to the Remote 1 operating temperature register.
2. As the temperature in that zone (Remote 1 temperature) rises toward and exceeds the operating point temperature,  $T_{MIN}$  is reduced and the fan speed increases.
3. As the temperature drops below the operating point temperature,  $T_{MIN}$  is increased and the fan speed is reduced.

However, the loop operation is not as simple as described in these steps. A number of conditions govern the situations in which  $T_{MIN}$  can increase or decrease.

### Short Cycle and Long Cycle

The ADT7468 implements two loops: a short cycle and a long cycle. The short cycle takes place every  $n$  monitoring cycles. The long cycle takes place every  $2n$  monitoring cycles. The value of  $n$  is programmable for each temperature channel. The bits are located at the following register locations:

Remote 1 = CYR1 = Bits <2:0> of Calibration Control Register 2 (Address = 0x37).

Local = CYL = Bits <5:3> of Calibration Control Register 2  
(Address = 0x37).

Remote 2 = CYR2 = Bits <7:6> of Calibration Control Register 2 and Bit 0 of Calibration Control Register 1 (Address = 0x36).

Table 15. Cycle Bit Assignments

| Code | Short Cycle |         | Long Cycle  |         |
|------|-------------|---------|-------------|---------|
| 000  | 8 cycles    | (1 s)   | 16 cycles   | (2 s)   |
| 001  | 16 cycles   | (2 s)   | 32 cycles   | (4 s)   |
| 010  | 32 cycles   | (4 s)   | 64 cycles   | (8 s)   |
| 011  | 64 cycles   | (8 s)   | 128 cycles  | (16 s)  |
| 100  | 128 cycles  | (16 s)  | 256 cycles  | (32 s)  |
| 101  | 256 cycles  | (32 s)  | 512 cycles  | (64 s)  |
| 110  | 512 cycles  | (64 s)  | 1024 cycles | (128 s) |
| 111  | 1024 cycles | (128 s) | 2048 cycles | (256 s) |

Care should be taken when choosing the cycle time. A long cycle time means that  $T_{MIN}$  is updated less often. If your system has very fast temperature transients, the dynamic  $T_{MIN}$  control loop will always be lagging. If you choose a cycle time that is too fast, the full benefit of changing  $T_{MIN}$  might not be realized and needs to change again on the next cycle; in effect, it is over-shooting. It is necessary to carry out some calibration to identify the most suitable response time.

Figure 71 shows the steps taken during the short cycle.

Figure 71. Short Cycle Steps

Figure 72 shows the steps taken during the long cycle.

The following examples illustrate some of the circumstances that might cause  $T_{MIN}$  to increase, decrease, or stay the same.

**Example: Normal Operation—No  $T_{MIN}$  Adjustment**

1. If measured temperature never exceeds the programmed operating point minus the hysteresis temperature, then  $T_{MIN}$  is not adjusted, that is, remains at its current setting.
2. If measured temperature never drops below the low temperature limit, then  $T_{MIN}$  is not adjusted.

Figure 72. Long Cycle Steps

Figure 73. Temperature between Operating Point and Low Temperature Limit

Because neither the operating point minus the hysteresis temperature nor the low temperature limit has been exceeded, the  $T_{MIN}$  value is not adjusted, and the fan runs at a speed determined by the fixed  $T_{MIN}$  and  $T_{RANGE}$  values defined in the automatic fan speed control mode.

**Example: Operating Point Exceeded— $T_{MIN}$  Reduced**

When the measured temperature is below the operating point temperature minus the hysteresis,  $T_{MIN}$  remains the same.

Once the temperature exceeds the operating temperature minus the hysteresis ( $OP - Hyst$ ),  $T_{MIN}$  starts to decrease. This occurs during the short cycle (see Figure 71). The rate at which  $T_{MIN}$  decreases depends on the programmed value of  $n$ . It also depends on how much the temperature has increased between this monitoring cycle and the last monitoring cycle, that is, if the temperature has increased by 1°C, then  $T_{MIN}$  is reduced by 2°C. Decreasing  $T_{MIN}$  has the effect of increasing the fan speed, thus providing more cooling to the system.

If the temperature is slowly increasing only in the range ( $OP - Hyst$ ), that is,  $\leq 0.25^\circ\text{C}$  per short monitoring cycle, then  $T_{MIN}$  does not decrease. This allows small changes in temperature in the desired operating zone without changing  $T_{MIN}$ . The long cycle makes no change to  $T_{MIN}$  in the

temperature range (OP – Hyst), because the temperature has not exceeded the operating temperature.

Once the temperature exceeds the operating temperature, the long cycle causes  $T_{MIN}$  to be reduced by 1°C every long cycle while the temperature remains above the operating temperature. This takes place in addition to the decrease in  $T_{MIN}$  that would occur due to the short cycle. In Figure 74, because the temperature is increasing at a rate  $\leq 0.25^\circ\text{C}$  per short cycle, no reduction in  $T_{MIN}$  takes place during the short cycle.

Once the temperature has fallen below the operating temperature,  $T_{MIN}$  stays the same. Even when the temperature starts to increase slowly,  $T_{MIN}$  stays the same, because the temperature increases at a rate  $\leq 0.25^\circ\text{C}$  per cycle.

## Example: Increase $T_{MIN}$ Cycle

When the temperature drops below the low temperature limit,  $T_{MIN}$  can increase in the long cycle. Increasing  $T_{MIN}$  has the effect of running the fan slower and, therefore, quieter. The long cycle diagram in Figure 74 shows the conditions that need to be true for  $T_{MIN}$  to increase. Here is a quick summary of those

conditions and the reasons they need to be true.

$T_{MIN}$  can increase, if

- The measured temperature has fallen below the low temperature limit. This means the user must choose the low limit carefully. It should not be so low that the temperature never falls below it, because  $T_{MIN}$  would never increase and the fans would run faster than necessary.
- $T_{MIN}$  is below the high temperature limit.  $T_{MIN}$  is never allowed to increase above the high temperature limit. As a result, the high limit should be sensibly chosen, because it determines how high  $T_{MIN}$  can go.
- $T_{MIN}$  is below the operating point temperature.  $T_{MIN}$  should never be allowed to increase above the operating point temperature, because the fans would not switch on until the temperature rose above the operating point.
- The temperature is above  $T_{MIN}$ . The dynamic  $T_{MIN}$  control is turned off below  $T_{MIN}$ .

Figure 74. Effect of Exceeding Operating Point Minus Hysteresis Temperature

Figure 75 shows how  $T_{MIN}$  increases when the current temperature is above  $T_{MIN}$  and below the low temperature limit, and  $T_{MIN}$  is below the high temperature limit and below the operating point. Once the temperature rises above the low temperature limit,  $T_{MIN}$  stays the same.

Figure 75. Increasing  $T_{MIN}$  for Quieter Operation

#### Example: Preventing $T_{MIN}$ from Reaching Full Scale

Because  $T_{MIN}$  is dynamically adjusted, it is undesirable for  $T_{MIN}$  to reach full scale (127°C), because the fan would never switch on. As a result,  $T_{MIN}$  is allowed to vary only within a specified range:

1. The lowest possible value for  $T_{MIN}$  is -127°C (twos complement mode) or -64°C (Offset 64 mode).
2.  $T_{MIN}$  cannot exceed the high temperature limit.
3. If the temperature is below  $T_{MIN}$ , the fan is switched off or is running at minimum speed, and dynamic  $T_{MIN}$  control is disabled.

Figure 76.  $T_{MIN}$  Adjustments Limited by the High Temperature Limit

## STEP 11: MONITORING THERM

Using the operating point limit ensures that the dynamic  $T_{MIN}$  control mode is operating in the best possible acoustic position while ensuring that the temperature never exceeds the maximum operating temperature. Using the operating point limit allows  $T_{MIN}$  to be independent of system-level issues because of its self-corrective nature. In PC design, the operating point for the chassis is usually the worst-case internal chassis temperature.

The optimal operating point for the processor is determined by monitoring the thermal monitor in the Intel Pentium 4 processor. To do this, the  $\overline{\text{PROCHOT}}$  output of the Pentium 4 is connected to the  $\overline{\text{THERM}}$  input of the ADT7468.

The operating point for the processor can be determined by allowing the current temperature to be copied to the operating point register when the  $\overline{\text{PROCHOT}}$  output pulls the  $\overline{\text{THERM}}$  input low on the ADT7468. This gives the maximum temperature at which the Pentium 4 can run before clock modulation occurs.

#### Enabling the $\overline{\text{THERM}}$ Trip Point as the Operating Point

Bits <4:2> of dynamic  $T_{MIN}$  control Register 1 (Reg. 0x36) enable/disable  $\overline{\text{THERM}}$  monitoring to program the operating point.

##### Dynamic $T_{MIN}$ Control Register 1 (0x36)

<2>  $\text{PHTR2} = 1$ , copies the Remote 2 current temperature to the Remote 2 operating point register, if  $\overline{\text{THERM}}$  is asserted.

The operating point contains the temperature at which  $\overline{\text{THERM}}$  is asserted. This allows the system to run as quietly as possible without affecting system performance.

$\text{PHTR2} = 0$ , ignores any  $\overline{\text{THERM}}$  assertions. The Remote 2 operating point register reflects its programmed value.

<3>  $\text{PHTL} = 1$ , copies the local current temperature to the local temperature operating point register, if  $\overline{\text{THERM}}$  is asserted. The operating point contains the temperature at which  $\overline{\text{THERM}}$  is asserted. This allows the system to run as quietly as possible without affecting system performance.

$\text{PHTL} = 0$ , ignores any  $\overline{\text{THERM}}$  assertions. The local temperature operating point register reflects its programmed value.

<4>  $\text{PHTR1} = 1$ , copies the Remote 1 current temperature to the Remote 1 operating point register, if  $\overline{\text{THERM}}$  is asserted. The operating point contains the temperature at which  $\overline{\text{THERM}}$  is asserted. This allows the system to run as quietly as possible without affecting system performance.

$\text{PHTR1} = 0$ , ignores any  $\overline{\text{THERM}}$  assertions. The Remote 1 operating point register reflects its programmed value.

#### Enabling Dynamic $T_{MIN}$ Control Mode

Bits <7:5> of dynamic  $T_{MIN}$  control Register 1 (Reg. 0x36) enable/disable dynamic  $T_{MIN}$  control on the temperature channels.

##### Dynamic $T_{MIN}$ Control Register 1 (0x36)

<5>  $\text{R2T} = 1$ , enables dynamic  $T_{MIN}$  control on the Remote 2 temperature channel. The chosen  $T_{MIN}$  value is dynamically adjusted based on the current temperature, operating point, and high and low limits for this zone.

**R2T = 0**, disables dynamic  $T_{MIN}$  control. The  $T_{MIN}$  value chosen is not adjusted and the channel behaves as described in the Automatic Fan Control Overview section.

**<6> LT = 1**, enables dynamic  $T_{MIN}$  control on the local temperature channel. The chosen  $T_{MIN}$  value is dynamically adjusted based on the current temperature, operating point, and high and low limits for this zone.

**LT = 0**, disables dynamic  $T_{MIN}$  control. The  $T_{MIN}$  value chosen is not adjusted and the channel behaves as described in the Automatic Fan Control Overview section.

**<7> R1T = 1**, enables dynamic  $T_{MIN}$  control on the Remote 1 temperature channel. The chosen  $T_{MIN}$  value is dynamically adjusted based on the current temperature, operating point, and high and low limits for this zone.

**R1T = 0**, disables dynamic  $T_{MIN}$  control. The  $T_{MIN}$  value chosen is not adjusted and the channel behaves as described in the Automatic Fan Control Overview section.

## ENHANCING SYSTEM ACOUSTICS

Automatic fan speed control mode reacts instantaneously to changes in temperature, that is, the PWM duty cycle responds immediately to temperature change. Any impulses in temperature can cause an impulse in fan noise. For psycho-acoustic reasons, the ADT7468 can prevent the PWM output from reacting instantaneously to temperature changes. Enhanced acoustic mode controls the maximum change in PWM duty cycle at a given time. The objective is to prevent the fan from cycling up and down, annoying the user.

### Acoustic Enhancement Mode Overview

Figure 77 gives a top-level overview of the automatic fan control circuitry on the ADT7468 and shows where acoustic enhancement fits in. Acoustic enhancement is intended as a postdesign tweak made by a system or mechanical engineer evaluating best settings for the system. Having determined the optimal settings for the thermal solution, the engineer can adjust the system acoustics. The goal is to implement a system that is acoustically pleasing without causing user annoyance due to fan cycling. It is important to realize that although a system might pass an acoustic noise requirement specification (for example, 36 dB), if the fan is annoying, it fails the consumer test.

Figure 77. Acoustic Enhancement Smooths Fan Speed Variations under Automatic Fan Speed Control

### Approaches to System Acoustic Enhancement

There are two different approaches to implementing system acoustic enhancement: temperature-centric and fan-centric.

The temperature-centric approach involves smoothing transient temperatures as they are measured by a temperature source (for example, Remote 1 temperature). The temperature values used to calculate the PWM duty cycle values are smoothed, reducing fan speed variation. However, this approach causes an inherent delay in updating fan speed and causes the thermal characteristics of the system to change. It also causes the system fans to stay on longer than necessary, because the fan's reaction is merely delayed. The user has no control over noise from different fans driven by the same temperature source. Consider, for example, a system in which control of a CPU cooler fan (on PWM1) and a chassis fan (on PWM2) use Remote 1 temperature. Because the Remote 1 temperature is smoothed, both fans are updated at exactly the same rate. If the chassis fan is much louder than the CPU fan, there is no way to improve its acoustics without changing the thermal solution of the CPU cooling fan.

The fan-centric approach to system acoustic enhancement controls the PWM duty cycle, driving the fan at a fixed rate (for example, 6%). Each time the PWM duty cycle is updated, it is incremented by a fixed 6%. As a result, the fan ramps smoothly to its newly calculated speed. If the temperature starts to drop, the PWM duty cycle immediately decreases by 6% at every update. Therefore, the fan ramps smoothly up or down without inherent system delay. Consider, for example, controlling the same CPU cooler fan (on PWM1) and chassis fan (on PWM2) using Remote 1 temperature. The  $T_{MIN}$  and  $T_{RANGE}$  settings have already been defined in automatic fan speed control mode, that is, thermal characterization of the control loop has been optimized. Now the chassis fan is noisier than the CPU cooling fan. Using the fan-centric approach, PWM2 can be placed into acoustic enhancement mode independently of PWM1. The acoustics of the chassis fan can, therefore, be adjusted without affecting the acoustic behavior of the CPU cooling fan, even though both fans are controlled by Remote 1 temperature. The fan-centric approach is how acoustic enhancement works on the ADT7468.

### Enabling Acoustic Enhancement for Each PWM Output

#### Enhance Acoustics Register 1 (Reg. 0x62)

<3> = 1, enables acoustic enhancement on PWM1 output.

#### Enhance Acoustics Register 2 (Reg. 0x63)

<7> = 1, enables acoustic enhancement on PWM2 output.

<3> = 1, enables acoustic enhancement on PWM3 output.

### Effect of Ramp Rate on Enhanced Acoustics Mode

The PWM signal driving the fan has a period,  $T$ , given by the PWM drive frequency,  $f$ , because  $T = 1/f$ . For a given PWM

period,  $T$ , the PWM period is subdivided into 255 equal time slots. One time slot corresponds to the smallest possible increment in the PWM duty cycle. A PWM signal of 33% duty cycle is, therefore, high for  $1/3 \times 255$  time slots and low for  $2/3 \times 255$  time slots. Therefore, a 33% PWM duty cycle corresponds to a signal that is high for 85 time slots and low for 170 time slots.

Figure 78. 33% PWM Duty Cycle Represented in Time Slots

The ramp rates in the enhanced acoustics mode are selectable from the values 1, 2, 3, 5, 8, 12, 24, and 48. The ramp rates are discrete time slots. For example, if the ramp rate is 8, then eight time slots are added to the PWM high duty cycle each time the PWM duty cycle needs to be increased. If the PWM duty cycle value needs to be decreased, it is decreased by eight time slots. Figure 79 shows how the enhanced acoustics mode algorithm operates.

Figure 79. Enhanced Acoustics Algorithm

The enhanced acoustics mode algorithm calculates a new PWM duty cycle based on the temperature measured. If the new PWM duty cycle value is greater than the previous PWM value, then the previous PWM duty cycle value is incremented by either 1, 2, 3, 5, 8, 12, 24, or 48 time slots, depending on the settings of the enhance acoustics registers. If the new PWM duty cycle value is less than the previous PWM value, then the previous PWM duty cycle is decremented by 1, 2, 3, 5, 8, 12, 24, or 48 time slots. Each time the PWM duty cycle is incremented or decremented, its value is stored as the previous PWM duty cycle for the next comparison.

A ramp rate of 1 corresponds to one time slot, which is  $1/255$  of the PWM period. In enhanced acoustics mode, incrementing or decrementing by 1 changes the PWM output by  $1/255 \times 100\%$ .

## STEP 12: RAMP RATE FOR ACOUSTIC ENHANCEMENT

The optimal ramp rate for acoustic enhancement can be found through system characterization after the thermal optimization has been finished. The effect of each ramp rate should be logged, if possible, to determine the best setting for a given solution.

### Enhanced Acoustics Register 1 (Reg. 0x62)

<2:0> ACOU, selects the ramp rate for PWM1.

- 000 = 1 time slot = 35 s
- 001 = 2 time slots = 17.6 s
- 010 = 3 time slots = 11.8 s
- 011 = 5 time slots = 7 s
- 100 = 8 time slots = 4.4 s
- 101 = 12 time slots = 3 s
- 110 = 24 time slots = 1.6 s
- 111 = 48 time slots = 0.8 s

### Enhance Acoustics Register 2 (Reg. 0x63)

<2:0> ACOU3, selects the ramp rate for PWM3.

- 000 = 1 time slot = 35 s
- 001 = 2 time slots = 17.6 s
- 010 = 3 time slots = 11.8 s
- 011 = 5 time slots = 7 s
- 100 = 8 time slots = 4.4 s
- 101 = 12 time slots = 3 s
- 110 = 24 time slots = 1.6 s
- 111 = 48 time slots = 0.8 s

<6:4> ACOU2, selects the ramp rate for PWM2.

- 000 = 1 time slot = 35 s
- 001 = 2 time slots = 17.6 s
- 010 = 3 time slots = 11.8 s
- 011 = 5 time slots = 7 s
- 100 = 8 time slots = 4.4 s
- 101 = 12 time slots = 3 s
- 110 = 24 time slots = 1.6 s
- 111 = 48 time slots = 0.8 s

Another way to view the ramp rates is to measure the time it takes for the PWM output to ramp up from 0% to 100% duty cycle for an instantaneous change in temperature. This can be tested by putting the ADT7468 into manual mode and changing the PWM output from 0% to 100% PWM duty cycle. The PWM output takes 35 s to reach 100%, when a ramp rate of 1 time slot is selected.

Figure 80 shows remote temperature plotted against PWM duty cycle for enhanced acoustics mode. The ramp rate is set to 48, which corresponds to the fastest ramp rate. Assume that a new

temperature reading is available every 115 ms. With these settings, it takes approximately 0.76 s to go from 33% duty cycle to 100% duty cycle (full speed). Even though the temperature increases very rapidly, the fan ramps up to full speed gradually.

Figure 80. Enhanced Acoustics Mode with Ramp Rate = 48

Figure 81 shows how changing the ramp rate from 48 to 8 affects the control loop. The overall response of the fan is slower. Because the ramp rate is reduced, it takes longer for the fan to achieve full running speed. In this case, it takes approximately 4.4 s for the fan to reach full speed.

Figure 81. Enhanced Acoustics Mode with Ramp Rate = 8

Figure 82 shows the PWM output response for a ramp rate of 2. In this instance, the fan took about 17.6 s to reach full running speed.

Figure 82. Enhanced Acoustics Mode with Ramp Rate = 2

Figure 83 shows how the control loop reacts to temperature with the slowest ramp rate. The ramp rate is set to 1, while all other control parameters remain the same. With the slowest ramp rate selected, it takes 35 s for the fan to reach full speed.

Figure 83. Enhanced Acoustics Mode with Ramp Rate = 1

As Figure 80 to Figure 83 show, the rate at which the fan reacts to temperature change is dependent on the ramp rate selected in the enhanced acoustics registers. The higher the ramp rate, the faster the fan reaches the newly calculated fan speed.

Figure 84 shows the behavior of the PWM output as temperature varies. As the temperature increases, the fan speed ramps up. Small drops in temperature do not affect the ramp-up function, because the newly calculated fan speed is still higher than the previous PWM value. Enhanced acoustics mode allows the PWM output to be made less sensitive to temperature variations. This is dependent on the ramp rate selected and programmed into the enhanced acoustics registers.

Figure 84. How Fan Reacts to Temperature Variation in Enhanced Acoustics Mode

### Slower Ramp Rates

The ADT7468 can be programmed for much longer ramp times by slowing the ramp rates. Each ramp rate can be slowed by a factor of 4.

#### PWM1 Configuration Register (Reg. 0x5C)

<3> SLOW, 1 slows the ramp rate for PWM1 by 4.

#### PWM2 Configuration Register (Reg. 0x5D)

<3> SLOW, 1 slows the ramp rate for PWM2 by 4.

#### PWM3 Configuration Register (Reg. 0x5E)

<3> SLOW, 1 slows the ramp rate for PWM3 by 4.

The following sections list the ramp-up times when the SLOW bit is set for each PWM output.

#### Enhanced Acoustics Register 1 (Reg. 0x62)

<2:0> ACOU, selects the ramp rate for PWM1.

|     |          |
|-----|----------|
| 000 | = 140 s  |
| 001 | = 70.4 s |
| 010 | = 47.2 s |
| 011 | = 28 s   |
| 100 | = 17.6 s |
| 101 | = 12 s   |
| 110 | = 6.4 s  |
| 111 | = 3.2 s  |

#### Enhance Acoustics Register 2 (Reg. 0x63)

<2:0> ACOU3, selects the ramp rate for PWM3.

|     |          |
|-----|----------|
| 000 | = 140 s  |
| 001 | = 70.4 s |
| 010 | = 47.2 s |
| 011 | = 28 s   |
| 100 | = 17.6 s |
| 101 | = 12 s   |
| 110 | = 6.4 s  |
| 111 | = 3.2 s  |

<6:4> ACOU2, selects the ramp rate for PWM2.

|     |          |
|-----|----------|
| 000 | = 140 s  |
| 001 | = 70.4 s |
| 010 | = 47.2 s |
| 011 | = 28 s   |
| 100 | = 17.6 s |
| 101 | = 12 s   |
| 110 | = 6.4 s  |
| 111 | = 3.2 s  |

## REGISTER TABLES

Table 16. ADT7468 Registers

| Address | R/W | Description                             | Bit 7                 | Bit 6       | Bit 5          | Bit 4 | Bit 3                    | Bit 2           | Bit 1                  | Bit 0   | Default | Lockable? |
|---------|-----|-----------------------------------------|-----------------------|-------------|----------------|-------|--------------------------|-----------------|------------------------|---------|---------|-----------|

**Table 17. Voltage Reading Registers (Power-On Default = 0x00)<sup>1</sup>**

| Register Address | R/W       | Description                                                                                                |
|------------------|-----------|------------------------------------------------------------------------------------------------------------|
| 0x20             | Read-only | Reflects the voltage measurement at the 2.5 V input on Pin 22 (8 MSBs of reading).                         |
| 0x21             | Read-only | Reflects the voltage measurement <sup>2</sup> at the V <sub>CCP</sub> input on Pin 23 (8 MSBs of reading). |
| 0x22             | Read-only | Reflects the voltage measurement <sup>3</sup> at the V <sub>CC</sub> input on Pin 4 (8 MSBs of reading).   |
| 0x23             | Read-only | Reflects the voltage measurement at the 5 V input on Pin 20 (8 MSBs of reading).                           |
| 0x24             | Read-only | Reflects the voltage measurement at the 12 V input on Pin 21 (8 MSBs of reading).                          |

<sup>1</sup>If the extended resolution bits of these readings are also being read, the extended resolution registers (Reg. 0x76, 0x77) must be read first. Once the extended resolution registers have been read, the associated MSB reading registers are frozen until read. Both the extended resolution registers and the MSB registers are frozen.

<sup>2</sup>If V<sub>CCP</sub>Low (Bit 1 of the Dynamic T<sub>MIN</sub> Control Register 1, 0x36) is set, V<sub>CCP</sub> can control the sleep state of the ADT7468.

<sup>3</sup>V<sub>CC</sub> (Pin 4) is the supply voltage for the ADT7468.

**Table 18. Temperature Reading Registers (Power-On Default = 0x01)<sup>1,2,3</sup>**

| Register Address | R/W       | Description                                                     |
|------------------|-----------|-----------------------------------------------------------------|
| 0x25             | Read-only | Remote 1 temperature reading <sup>3,4</sup> (8 MSB of reading). |
| 0x26             | Read-only | Local temperature reading (8 MSB of reading).                   |
| 0x27             | Read-only | Remote 2 temperature reading <sup>3,4</sup> (8 MSB of reading). |

<sup>1</sup> If the extended resolution bits of these readings are also being read, the extended resolution registers (Reg. 0x76, 0x77) must be read first. Once the extended resolution registers have been read, all associated MSB reading registers are frozen until read. Both the extended resolution registers and the MSB registers are frozen.

<sup>2</sup> These temperature readings can be in twos complement or Offset 64 format; this interpretation is determined by Bit 0 of Configuration Register 5 (0x7C).

<sup>3</sup> In twos complement mode, a temperature reading of –128°C (0x80) indicates a diode fault (open or short) on that channel.

<sup>4</sup> In Offset 64 mode, a temperature reading of –64°C (0x00) indicates a diode fault (open or short) on that channel.

**Table 19. Fan Tachometer Reading Registers (Power-On Default = 0x00)<sup>1</sup>**

| Register Address | R/W       | Description      |
|------------------|-----------|------------------|
| 0x28             | Read-only | TACH1 low byte.  |
| 0x29             | Read-only | TACH1 high byte. |
| 0x2A             | Read-only | TACH2 low byte.  |
| 0x2B             | Read-only | TACH2 high byte. |
| 0x2C             | Read-only | TACH3 low byte.  |
| 0x2D             | Read-only | TACH3 high byte. |
| 0x2E             | Read-only | TACH4 low byte.  |
| 0x2F             | Read-only | TACH4 high byte. |

<sup>1</sup> These registers count the number of 11.11  $\mu$ s periods (based on an internal 90 kHz clock) that occur between a number of consecutive fan TACH pulses (default = 2). The number of TACH pulses used to count can be changed using the fan pulses per revolution register (Reg. 0x7B). This allows the fan speed to be accurately measured. Because a valid fan tachometer reading requires that two bytes are read, the low byte *must* be read first. Both the low and high bytes are then frozen until read. At power-on, these registers contain 0x0000 until such time as the first valid fan TACH measurement is read into these registers. This prevents false interrupts from occurring while the fans are spinning up. A count of 0xFFFF indicates that a fan is one of the following:

- Stalled or blocked (object jamming the fan).
- Failed (internal circuitry destroyed).
- Not populated. (The ADT7468 expects to see a fan connected to each TACH. If a fan is not connected to that TACH, its TACH minimum high and low bytes should be set to 0xFFFF.)
- Alternate function, for example, TACH4 reconfigured as  $\overline{\text{THERM}}$  pin.
- 2-wire instead of 3-wire fan.

**Table 20. Current PWM Duty Cycle Registers (Power-On Default = 0x00)<sup>1</sup>**

| Register Address | R/W        | Description                                                     |
|------------------|------------|-----------------------------------------------------------------|
| 0x30             | Read/write | PWM1 current duty cycle (0% to 100% duty cycle = 0x00 to 0xFF). |
| 0x31             | Read/write | PWM2 current duty cycle (0% to 100% duty cycle = 0x00 to 0xFF). |
| 0x32             | Read/write | PWM3 current duty cycle (0% to 100% duty cycle = 0x00 to 0xFF). |

<sup>1</sup> These registers reflect the PWM duty cycle driving each fan at any given time. When in automatic fan speed control mode, the ADT7468 reports the PWM duty cycles back through these registers. The PWM duty cycle values vary according to temperature in automatic fan speed control mode. During fan startup, these registers report back 0x00. In software mode, the PWM duty cycle outputs can be set to any duty cycle value by writing to these registers.

**Table 21. Operating Point Registers (Power-On Default = 0x64)<sup>1,2,3</sup>**

| Register Address | R/W <sup>3</sup> | Description                                                   |
|------------------|------------------|---------------------------------------------------------------|
| 0x33             | Read/write       | Remote 1 operating point register (default = 100°C).          |
| 0x34             | Read/write       | Local temperature operating point register (default = 100°C). |
| 0x35             | Read/write       | Remote 2 operating point register (default = 100°C).          |

<sup>1</sup> These registers set the target operating point for each temperature channel when the dynamic  $T_{\text{MIN}}$  control feature is enabled.

<sup>2</sup> The fans being controlled are adjusted to maintain temperature about an operating point.

<sup>3</sup> These registers become read-only when the Configuration Register 1 lock bit is set to 1. Any subsequent attempts to write to these registers fail.

Table 22. Register 0x36—Dynamic T<sub>MIN</sub> Control Register 1 (Power-On Default = 0x00)<sup>1</sup>

| Bit | Name                | R/W        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|---------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0> | CYR2                | Read/write | MSB of 3-bit remote 2 cycle value. The other two bits of the code reside in Dynamic T <sub>MIN</sub> Control Register 2 (Reg. 0x37). These three bits define the delay time between making subsequent T <sub>MIN</sub> adjustments in the control loop, in terms of the number of monitoring cycles. The system has associated thermal time constants that need to be found to optimize the response of fans and the control loop.                                                                                                                                                                                                  |
| <1> | V <sub>CCP</sub> LO | Read/write | V <sub>CCP</sub> LO = 1. When the power is supplied from 3.3 V STANDBY and the core voltage (V <sub>CCP</sub> ) drops below its V <sub>CCP</sub> low limit value (Reg. 0x46), the following occurs: <ul style="list-style-type: none"> <li>• Status Bit 1 in Status Register 1 is set.</li> <li>• <u>SMBALERT</u> is generated, if enabled.</li> <li>• <u>PROCHOT</u> monitoring is disabled.</li> <li>• Dynamic T<sub>MIN</sub> control is disabled.</li> <li>• The device is prevented from entering shutdown.</li> <li>• Everything is re-enabled once V<sub>CCP</sub> increases above the V<sub>CCP</sub> low limit.</li> </ul> |
| <2> | PHTR1               | Read/write | PHTR1 = 1 copies the Remote 1 current temperature to the Remote 1 operating point register, if <u>THERM</u> is asserted. The operating point contains the temperature at which <u>THERM</u> is asserted, which allows the system to run as quietly as possible without affecting system performance.<br>PHTR1 = 0 ignores any <u>THERM</u> assertions on the <u>THERM</u> pin. The Remote 1 operating point register reflects its programmed value.                                                                                                                                                                                 |
| <3> | PHTL                | Read/write | PHTL = 1 copies the local channel's current temperature to the local operating point register, if <u>THERM</u> is asserted. The operating point contains the temperature at which <u>THERM</u> is asserted, which allows the system to run as quietly as possible without affecting system performance.<br>PHTL = 0 ignores any <u>THERM</u> assertions on the <u>THERM</u> pin. The local operating temperature point register reflects its programmed value.                                                                                                                                                                      |
| <4> | PHTR2               | Read/write | PHTR2 = 1 copies the Remote 2 current temperature to the Remote 2 operating point register, if <u>THERM</u> is asserted. The operating point contains the temperature at which <u>THERM</u> is asserted. This allows the system to run as quietly as possible without affecting system performance.<br>PHTR2 = 0 ignores any <u>THERM</u> assertions on the <u>THERM</u> pin. The Remote 2 operating point register reflects its programmed value.                                                                                                                                                                                  |
| <5> | R1T                 | Read/write | R1T = 1 enables dynamic T <sub>MIN</sub> control on the Remote 1 temperature channel. The chosen T <sub>MIN</sub> value is dynamically adjusted based on the current temperature, operating point, and high and low limits for this zone.<br>R1T = 0 disables dynamic T <sub>MIN</sub> control. The T <sub>MIN</sub> value chosen is not adjusted, and the channel behaves as described in the Fan Speed Control section.                                                                                                                                                                                                           |
| <6> | LT                  | Read/write | LT=1 enables dynamic T <sub>MIN</sub> control on the local temperature channel. The chosen T <sub>MIN</sub> value is dynamically adjusted based on the current temperature, operating point, and high and low limits for this zone.<br>LT = 0 disables dynamic T <sub>MIN</sub> control. The T <sub>MIN</sub> value chosen is not adjusted, and the channel behaves as described in the Fan Speed Control section.                                                                                                                                                                                                                  |
| <7> | R2T                 | Read/write | R2T = 1 enables dynamic T <sub>MIN</sub> control on the Remote 2 temperature channel. The chosen T <sub>MIN</sub> value is dynamically adjusted based on the current temperature, operating point, and high and low limits for this zone.<br>R2T = 0 disables dynamic T <sub>MIN</sub> control. The T <sub>MIN</sub> value chosen is not adjusted, and the channel behaves as described in the Fan Speed Control section.                                                                                                                                                                                                           |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any subsequent attempts to write to this register fail.

**Table 23. Register 0x37—Dynamic T<sub>MIN</sub> Control Register 2 (Power-On Default = 0x00)<sup>1</sup>**

| Bit   | Name | R/W        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2:0> | CYR1 | Read/write | 3-Bit Remote 1 Cycle Value. These three bits define the delay time between making subsequent T <sub>MIN</sub> adjustments in the control loop for the Remote 1 channel, in terms of number of monitoring cycles. The system has associated thermal time constants that need to be found to optimize the response of fans and the control loop.                                                                                                         |
|       |      | Bits       | Decrease Cycle      Increase Cycle                                                                                                                                                                                                                                                                                                                                                                                                                     |
|       |      | 000        | 8 cycles (1 s)      16 cycles (2 s)                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <7:6> | CYR2 | Read/write | 2 LSBs of 3-bit Remote 2 cycle value. The MSB of the 3-bit code resides in Dynamic T <sub>MIN</sub> Control Register 1 (Reg. 0x36). These three bits define the delay time between making subsequent T <sub>MIN</sub> adjustments in the control loop for the Remote 2 channel, in terms of number of monitoring cycles. The system has associated thermal time constants that need to be found to optimize the response of fans and the control loop. |

|       |      | 110        | 512 cycles (64 s)      1024 cycles (128 s)                                                                                                                                                                                                                                                                                                                                                                                                             |
|       |      | 111        | 1024 cycles (128 s)      2048 cycles (256 s)                                                                                                                                                                                                                                                                                                                                                                                                           |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any subsequent attempts to write to this register fail.

**Table 24. Maximim PWM Duty Cycle (Power-On Default = 0xFF)<sup>1,2</sup>**

| Register Address | R/W <sup>2</sup> | Description                                                |
|------------------|------------------|------------------------------------------------------------|
| 0x38             | Read/write       | Maximum duty cycle for PWM1 output, default = 100% (0xFF). |
| 0x39             | Read/write       | Maximum duty cycle for PWM2 output, default = 100% (0xFF). |
| 0x3A             | Read/write       | Maximum duty cycle for PWM3 output, default = 100% (0xFF). |

<sup>1</sup>These registers set the maximum PWM duty cycle of the PWM output.

<sup>2</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any subsequent attempts to write to this register fail.

# ADT7468

**Table 25. Register 0x40—Configuration Register 1 (Power-On Default = 0x01)**

| Bit | Name   | R/W        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|--------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0> | STRT   | Read/write | Logic 1 enables monitoring and PWM control outputs based on the limit settings programmed. Logic 0 disables monitoring and PWM control based on the default power-up limit settings. Note that the limit values programmed are preserved even if a Logic 0 is written to this bit and the default settings are enabled. This bit becomes read-only and cannot be changed once Bit 1 (LOCK bit) has been written. All limit registers should be programmed by BIOS before setting this bit to 1. (Lockable.) |
| <1> | LOCK   | Write once | Logic 1 locks all limit values to their current settings. Once this bit is set, all lockable registers become read-only and cannot be modified until the ADT7468 is powered down and powered up again. This prevents rogue programs such as viruses from modifying critical system limit settings. (Lockable.)                                                                                                                                                                                              |
| <2> | RDY    | Read-only  | This bit is set to 1 by the ADT7468 to indicate only that the device is fully powered-up and ready to begin system monitoring.                                                                                                                                                                                                                                                                                                                                                                              |
| <3> | FSPD   | Read/write | When set to 1, this bit runs all fans at full speed. Power-on default = 0. This bit never gets locked.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <4> | Vxl    | Read/write | BIOS should set this bit to a 1 when the ADT7468 is configured to measure current from an ADI ADOPT™ VRM controller and to measure the CPU's core voltage. This bit allows monitoring software to display CPU watts usage. (Lockable.)                                                                                                                                                                                                                                                                      |
| <5> | FSPDIS | Read/write | Logic 1 disables fan spin-up for two TACH pulses. Instead, the PWM outputs go high for the entire fan spin-up timeout selected.                                                                                                                                                                                                                                                                                                                                                                             |
| <6> | TODIS  | Read/write | When this bit is set to 1, the SMBus timeout feature is enabled. This allows the ADT7468 to be used with SMBus controllers that cannot handle SMBus timeouts. (Lockable.)                                                                                                                                                                                                                                                                                                                                   |
| <7> | Vcc    | Read/write | When this bit is set to 1, the ADT7468 rescales its Vcc pin to measure 5 V supply. If this bit is 0, the ADT7468 measures Vcc as a 3.3 V supply. (Lockable.)                                                                                                                                                                                                                                                                                                                                                |

**Table 26. Register 0x41—Interrupt Status Register 1 (Power-On Default = 0x00)**

| Bit | Name                   | R/W       | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0> | 2.5 V                  | Read-only | 2.5 V = 1 indicates that the 2.5 V high or low limit has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided.                                                                                                                                                                                                                                               |
| <1> | V <sub>CCP</sub>       | Read-only | V <sub>CCP</sub> = 1 indicates that the V <sub>CCP</sub> high or low limit has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided.                                                                                                                                                                                                                         |
| <2> | V <sub>CC</sub>        | Read-only | V <sub>CC</sub> = 1 indicates that the V <sub>CC</sub> high or low limit has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided.                                                                                                                                                                                                                           |
| <3> | 5 V/<br>THERM<br>timer | Read-only | A one indicates the 5 V high or low limit has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided. If Pin 20 is configured as THERM, this bit is asserted when the Timer Limit has been exceeded.                                                                                                                                                           |
| <4> | R1T                    | Read-only | R1T = 1 indicates that the Remote 1 low or high temperature has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided.                                                                                                                                                                                                                                        |
| <5> | LT                     | Read-only | LT = 1 indicates that the local low or high temperature has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided.                                                                                                                                                                                                                                            |
| <6> | R2T                    | Read-only | R2T = 1 indicates that the Remote 2 low or high temperature has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided.                                                                                                                                                                                                                                        |
| <7> | OOL                    | Read-only | OOL = 1 indicates that an out-of-limit event has been latched in Status Register 2. This bit is a logical OR of all status bits in Status Register 2. Software can test this bit in isolation to determine whether any of the voltage, temperature, or fan speed readings represented by Status Register 2 are out-of-limit, which saves the need to read Status Register 2 during every interrupt or polling cycle. |

**Table 27. Register 0x42—Interrupt Status Register 2 (Power-On Default = 0x00)**

| Bit | Name   | R/W        | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|--------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0> | 12V/VC | Read-only  | A one indicates that the 12 V high or low limit has been exceeded. This bit is cleared on a read of the status register only if the error condition has subsided. If Pin 21 is configured as VID5, this bit is the VID change bit. This bit is set when the levels on VID0 to VID5 are different than they were 11 $\mu$ s previously. This pin can be used to generate an SMBALERT whenever the VID code changes. |
| <1> | OVT    | Read-only  | OVT = 1 indicates that one of the $\overline{\text{THERM}}$ overtemperature limits has been exceeded. This bit is cleared on a read of the status register when the temperature drops below $\overline{\text{THERM}} - T_{\text{HYST}}$ .                                                                                                                                                                          |
| <2> | FAN1   | Read-only  | FAN1 = 1 indicates that Fan 1 has dropped below minimum speed or has stalled. This bit is <i>not</i> set when the PWM 1 output is off.                                                                                                                                                                                                                                                                             |
| <3> | FAN2   | Read-only  | FAN2 = 1 indicates that Fan 2 has dropped below minimum speed or has stalled. This bit is <i>not</i> set when the PWM 2 output is off.                                                                                                                                                                                                                                                                             |
| <4> | FAN3   | Read-only  | FAN3 = 1 indicates that Fan 3 has dropped below minimum speed or has stalled. This bit is <i>not</i> set when the PWM 3 output is off.                                                                                                                                                                                                                                                                             |
| <5> | F4P    | Read-only  | When Pin 14 is programmed as a TACH4 input, F4P = 1 indicates that Fan 4 has dropped below minimum speed or has stalled. This bit is <i>not</i> set when the PWM3 output is off.                                                                                                                                                                                                                                   |
|     |        | Read/write | When Pin 14 is programmed as a GPIO output, writing to this bit determines the logic output of the GPIO.                                                                                                                                                                                                                                                                                                           |
|     |        | Read-only  | If Pin 14 is configured as the $\overline{\text{THERM}}$ timer input for $\overline{\text{THERM}}$ monitoring, then this bit is set when the $\overline{\text{THERM}}$ assertion time exceeds the limit programmed in the $\overline{\text{THERM}}$ limit register (Reg. 0x7A).                                                                                                                                    |
| <6> | D1     | Read-only  | D1 = 1 indicates either an open or short circuit on the Thermal Diode 1 inputs.                                                                                                                                                                                                                                                                                                                                    |
| <7> | D2     | Read-only  | D2 = 1 indicates either an open or short circuit on the Thermal Diode 2 inputs.                                                                                                                                                                                                                                                                                                                                    |

**Table 28. Register 43H—VID Register (Power-On Default = 0x00 )**

| Bit   | Name     | R/W        | Description                                                                                                                                                                                                                                                                                        |
|-------|----------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <4:0> | VID[4:0] | Read-only  | The VID[4:0] inputs from the CPU indicate the expected processor core voltage. On power-up, these bits reflect the state of the VID pins, even if monitoring is not enabled.                                                                                                                       |
| <5>   | VID5     | Read-only  | Reads VID5 from the CPU when Bit 7 = 1. If Bit 7 = 0, then the VID5 bit always reads back 0 (power-on default).                                                                                                                                                                                    |
| <6>   | THLD     | Read/write | Selects the input switching threshold for the VID inputs.<br>THLD = 0 selects a threshold of 1 V ( $V_{\text{OL}} < 0.8 \text{ V}$ , $V_{\text{IH}} > 1.7 \text{ V}$ ).<br>THLD = 1 lowers the switching threshold to 0.6 V ( $V_{\text{OL}} < 0.4 \text{ V}$ , $V_{\text{IH}} > 0.8 \text{ V}$ ). |
| <7>   | VIDSEL   | Read/write | VIDSEL = 0 configures Pin 21 as the 12 V measurement input (default).                                                                                                                                                                                                                              |

**Table 29. Voltage Limit Registers<sup>1</sup>**

| Register Address | R/W        | Description <sup>2</sup>     | Power-On Default |
|------------------|------------|------------------------------|------------------|
| 0x44             | Read/write | 2.5 V.                       | 0x00             |
| 0x45             | Read/write | 2.5 V.                       | 0xFF             |
| 0x46             | Read/write | $V_{\text{CCP}}$ low limit.  | 0x00             |
| 0x47             | Read/write | $V_{\text{CCP}}$ high limit. | 0xFF             |
| 0x48             | Read/write | $V_{\text{CC}}$ low limit.   | 0x00             |
| 0x49             | Read/write | $V_{\text{CC}}$ high limit.  | 0xFF             |
| 0x4A             | Read/write | 5 V low limit.               | 0x00             |
| 0x4B             | Read/write | 5 V high limit.              | 0xFF             |
| 0x4C             | Read/write | 12 V low limit.              | 0x00             |
| 0x4D             | Read/write | 12 V high limit.             | 0xFF             |

<sup>1</sup>Setting the Configuration Register 1 lock bit has no effect on these registers.<sup>2</sup>High Limits: An interrupt is generated when a value exceeds its high limit (> comparison). Low Limits: An interrupt is generated when a value is equal to or below its low limit ( $\leq$  comparison).

**Table 30. Temperature Limit Registers<sup>1</sup>**

| Register Address | R/W        | Description <sup>2</sup>         | Power-On Default |
|------------------|------------|----------------------------------|------------------|
| 0x4E             | Read/write | Remote 1 temperature low limit.  | 0x81             |
| 0x4F             | Read/write | Remote 1 temperature high limit. | 0x7F             |
| 0x50             | Read/write | Local temperature low limit.     | 0x81             |
| 0x51             | Read/write | Local temperature high limit.    | 0x7F             |
| 0x52             | Read/write | Remote 2 temperature low limit.  | 0x81             |
| 0x53             | Read/write | Remote 2 temperature high limit. | 0x7F             |

<sup>1</sup> Exceeding any of these temperature limits by 1°C causes the appropriate status bit to be set in the interrupt status register. Setting the Configuration Register 1 lock bit has no effect on these registers.

<sup>2</sup> High Limits: An interrupt is generated when a value exceeds its high limit (> comparison). Low Limits: An interrupt is generated when a value is equal to or below its low limit (≤ comparison).

**Table 31. Fan Tachometer Limit Registers<sup>1</sup>**

| Register Address | R/W        | Description                                                | Power-On Default |
|------------------|------------|------------------------------------------------------------|------------------|
| 0x54             | Read/write | TACH1 minimum low byte.                                    | 0xFF             |
| 0x55             | Read/write | TACH1 minimum high byte/Single channel ADC channel select. | 0xFF             |
| 0x56             | Read/write | TACH2 minimum low byte.                                    | 0xFF             |
| 0x57             | Read/write | TACH2 minimum high byte.                                   | 0xFF             |
| 0x58             | Read/write | TACH3 minimum low byte.                                    | 0xFF             |
| 0x59             | Read/write | TACH3 minimum high byte.                                   | 0xFF             |
| 0x5A             | Read/write | TACH4 minimum low byte.                                    | 0xFF             |
| 0x5B             | Read/write | TACH4 minimum high byte.                                   | 0xFF             |

<sup>1</sup> Exceeding any of the TACH limit registers by 1 indicates that the fan is running too slowly or has stalled. The appropriate status bit is set in Interrupt Status Register 2 to indicate the fan failure. Setting the Configuration Register 1 lock bit has no effect on these registers.

**Table 32. Register 0x55—TACH 1 Minimum High Byte (Power-On Default = 0xFF)**

| Bits  | Name     | R/W        | Description                                                                                                                                                                                                                               |
|-------|----------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <4:0> | Reserved | Read-only  | These bits are reserved when Bit 6 of Config 2 Register (0x73) is set (single-channel ADC mode). Otherwise, these bits represent Bits <4:0> of the TACH1 minimum high byte.                                                               |
| <7:5> | SCADC    | Read/write | When Bit 6 of Config 2 Register (0x73) is set (single channel ADC mode), these bits are used to select the only channel from which the ADC makes measurements. Otherwise, these bits represent Bits <7:5> of the TACH1 minimum high byte. |

Table 33. PWM Configuration Registers

| Register Address |      | R/W <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Power-On Default |

| Bit              | Name | R/W              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |
| <2:0>            | SPIN | Read/write       | These bits control the startup timeout for PWMx. The PWM output stays high until two valid TACH rising edges are seen from the fan. If there is not a valid TACH signal during the fan TACH measurement directly after the fan startup timeout period, then the TACH measurement reads 0xFFFF and Status Register 2 reflects the fan fault. If the TACH minimum high and low bytes contain 0xFFFF or 0x0000, then the Status Register 2 bit is not set, even if the fan has not started.<br>000 = No startup timeout<br>001 = 100 ms<br>010 = 250 ms (default)<br>011 = 400 ms<br>100 = 667 ms<br>101 = 1 s<br>110 = 2 s<br>111 = 4 s          |                  |
| <3>              | SLOW | Read/write       | SLOW = 1 makes the ramp rates for acoustic enhancement four times longer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |
| <4>              | INV  | Read/write       | This bit inverts the PWM output. The default is 0, which corresponds to a logic high output for 100% duty cycle. Setting this bit to 1 inverts the PWM output, so 100% duty cycle corresponds to a logic low output.                                                                                                                                                                                                                                                                                                                                                                                                                           |                  |
| <7:5>            | BHVR | Read/write       | These bits assign each fan to a particular temperature sensor for localized cooling.<br>000 = Remote 1 temperature controls PWMx (automatic fan control mode).<br>001 = local temperature controls PWMx (automatic fan control mode).<br>010 = Remote 2 temperature controls PWMx (automatic fan control mode).<br>011 = PWMx runs full speed.<br>100 = PWMx disabled (default).<br>101 = fastest speed calculated by local and Remote 2 temperature controls PWMx.<br>110 = fastest speed calculated by all three temperature channel controls PWMx.<br>111 = manual mode. PWM duty cycle registers (Reg. 0x30 to Reg. 0x32) become writable. |                  |

<sup>1</sup>These registers become read-only when the Configuration Register 1 lock bit is set to 1. Any subsequent attempts to write to these registers fail.

Table 34. TEMP T<sub>RANGE</sub>/PWM Frequency Registers

| Register Address |       | R/W <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Power-On Default |

| <2:0>            | FREQ  | Read/write       | These bits control the PWMx frequency.<br>000 = 11.0 Hz<br>001 = 14.7 Hz<br>010 = 22.1 Hz<br>011 = 29.4 Hz<br>100 = 35.3 Hz (default)<br>101 = 44.1 Hz<br>110 = 58.8 Hz<br>111 = 88.2 Hz                                                                                                                                                                                                                                                                                                                                                                                       |                  |
| <3>              | THRM  | Read/write       | THRM = 1 causes the <u>THERM</u> pin (Pin 14/20) to assert low as an output when this temperature channel's <u>THERM</u> limit has been exceeded by 0.25°C. The <u>THERM</u> pin remains asserted until the temperature is equal to or below the <u>THERM</u> limit. The minimum time that <u>THERM</u> asserts is one monitoring cycle. This allows clock modulation of devices that incorporate this feature.<br><br>THRM = 0 makes the <u>THERM</u> pin act as an input only, for example, for Pentium 4 PROCHOT monitoring, when Pin 14/20 is configured as <u>THERM</u> . |                  |
| <7:4>            | RANGE | Read/write       | These bits determine the PWM duty cycle vs. the temperature slope for automatic fan control.<br>0000 = 2°C<br>0001 = 2.5°C<br>0010 = 3.33°C<br>0011 = 4°C<br>0100 = 5°C<br>0101 = 6.67°C<br>0110 = 8°C<br>0111 = 10°C<br>1000 = 13.33°C<br>1001 = 16°C<br>1010 = 20°C<br>1011 = 26.67°C<br>1100 = 32°C (Default)<br>1101 = 40°C<br>1110 = 53.33°C<br>1111 = 80°C                                                                                                                                                                                                               |                  |

<sup>1</sup>These registers become read-only when the Configuration Register 1 lock bit is set. Any further attempts to write to these registers have no effect.

Table 35. Register 0x62—Enhanced Acoustics Register 1 (Power-On Default = 0x00)

| Bit      | Name  | R/W <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                   |                             |
|----------|-------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| <2:0>    | ACOU  | Read/write       | These bits select the ramp rate applied to the PWM1 output. Instead of PWM1 jumping instantaneously to its newly calculated speed, PWM1 ramps gracefully at the rate determined by these bits. This feature enhances the acoustics of the fan being driven by the PWM1 output.                                                                                |                             |

|                |              |                  | 100 = 8                                                                                                                                                                                                                                                                        | 4.4 s                       |
|                |              |                  | 101 = 12                                                                                                                                                                                                                                                                       | 3 s                         |
| 110 = 24       | 1.6 s        |                  |                                                                                                                                                                                                                                                                                |                             |
| <7>            | EN2          | Read/write       | When this bit is 1, acoustic enhancement is enabled on PWM2 output.                                                                                                                                                                                                            |                             |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

**Table 37. PWM Minimum Duty Cycle Registers**

| Register Address | R/W <sup>1</sup> | Description              | Power-On Default                                                                                                                                                                                 |
|------------------|------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x64             | Read/write       | PWM1 minimum duty cycle. | 0x80 (50% duty cycle)                                                                                                                                                                            |
| 0x65             | Read/write       | PWM2 minimum duty cycle. | 0x80 (50% duty cycle)                                                                                                                                                                            |
| 0x66             | Read/write       | PWM3 minimum duty cycle. | 0x80 (50% duty cycle)                                                                                                                                                                            |
| Bit              | Name             | R/W <sup>1</sup>         | Description                                                                                                                                                                                      |
| <7:0>            | PWM duty cycle   | Read/write               | These bits define the PWM <sub>MIN</sub> duty cycle for PWMx.<br>0x00 = 0% duty cycle (fan off).<br>0x40 = 25% duty cycle.<br>0x80 = 50% duty cycle.<br>0xFF = 100% duty cycle (fan full speed). |

<sup>1</sup>These registers become read-only when the ADT7468 is in automatic fan control mode.

**Table 38. T<sub>MIN</sub> Registers<sup>1</sup>**

| Register Address | R/W <sup>2</sup> | Description                             | Power-On Default |
|------------------|------------------|-----------------------------------------|------------------|
| 0x67             | Read/write       | Remote 1 temperature T <sub>MIN</sub> . | 0x5A (90°C)      |
| 0x68             | Read/write       | Local temperature T <sub>MIN</sub> .    | 0x5A (90°C)      |
| 0x69             | Read/write       | Remote 2 temperature T <sub>MIN</sub> . | 0x5A (90°C)      |

<sup>1</sup>These are the T<sub>MIN</sub> registers for each temperature channel. When the temperature measured exceeds T<sub>MIN</sub>, the appropriate fan runs at minimum speed and increases with temperature according to T<sub>RANGE</sub>.

<sup>2</sup>These registers become read-only when the Configuration Register 1 lock bit is set. Any further attempts to write to these registers have no effect.

Table 39. THERM Limit Registers<sup>1</sup>

| Register Address | R/W <sup>2</sup> | Description           | Power-On Default |
|------------------|------------------|-----------------------|------------------|
| 0x6A             | Read/write       | Remote 1 THERM limit. | 0x64 (100°C)     |
| 0x6B             | Read/write       | Local THERM limit.    | 0x64 (100°C)     |
| 0x6C             | Read/write       | Remote 2 THERM limit. | 0x64 (100°C)     |

<sup>1</sup>If any temperature measured exceeds its THERM limit, all PWM outputs drive their fans at 100% duty cycle. This is a fail-safe mechanism incorporated to cool the system in the event of a critical overtemperature. It also ensures some level of cooling in the event that software or hardware locks up. If set to 0x80, this feature is disabled. The PWM output remains at 100% until the temperature drops below THERM limit – hysteresis. If the THERM pin is programmed as an output, then exceeding these limits by 0.25°C can cause the THERM pin to assert low as an output.

<sup>2</sup>These registers become read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to these registers have no effect.

Table 40. Temperature/T<sub>MIN</sub> Hysteresis Registers<sup>1</sup>

| Register Address | R/W <sup>2</sup>    | Description                                                                                                                                                                                   | Power-On Default |
|------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 0x6D<br><3:0>    | Read/write<br>HYSL  | Remote 1 and local temperature hysteresis.<br>Local temperature hysteresis. 0°C to 15°C of hysteresis can be applied to the local temperature AFC and dynamic T <sub>MIN</sub> control loops. | 0x44             |
| <7:4>            | HYSR1               | Remote 1 temperature hysteresis. 0°C to 15°C of hysteresis can be applied to the Remote 1 temperature AFC and dynamic T <sub>MIN</sub> control loops.                                         | 0x40             |
| 0x6E<br><7:4>    | Read/write<br>HYSR2 | Remote 2 temperature hysteresis.<br>Local temperature hysteresis. 0°C to 15°C of hysteresis can be applied to the local temperature AFC and dynamic T <sub>MIN</sub> control loops.           |                  |

<sup>1</sup>Each 4-bit value controls the amount of temperature hysteresis applied to a particular temperature channel. Once the temperature for that channel falls below its T<sub>MIN</sub> value, the fan remains running at PWM<sub>MIN</sub> duty cycle until the temperature = T<sub>MIN</sub> – hysteresis. Up to 15°C of hysteresis can be assigned to any temperature channel. The hysteresis value chosen also applies to that temperature channel, if its THERM limit is exceeded. The PWM output being controlled goes to 100%, if the THERM limit is exceeded and remains at 100% until the temperature drops below THERM – hysteresis. For acoustic reasons, it is recommended that the hysteresis value not be programmed less than 4°C. Setting the hysteresis value lower than 4°C causes the fan to switch on and off regularly when the temperature is close to T<sub>MIN</sub>.

<sup>2</sup>These registers become read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to these registers have no effect.

Table 41. XNOR Tree Test Enable

| Register Address | R/W <sup>1</sup>  | Description                                                                                                                                                                 | Power-On Default |
|------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 0x6F<br><0>      | Read/write<br>XEN | XNOR tree test enable register.<br>If the XEN bit is set to 1, the device enters the XNOR tree test mode. Clearing the bit removes the device from the XNOR tree test mode. | 0x00             |
| <7:1>            | Reserved          | Unused. Do not write to these bits.                                                                                                                                         |                  |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

Table 42. Remote 1 Temperature Offset

| Register Address | R/W <sup>1</sup>         | Description                                                                                                                                                                                                                                                    | Power-On Default |
|------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 0x70<br><7:0>    | Read/write<br>Read/write | Remote 1 temperature offset.<br>Allows a twos complement offset value to be automatically added to or subtracted from the Remote 1 temperature reading. This is to compensate for any inherent system offsets such as PCB trace resistance. LSB value = 0.5°C. | 0x00             |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

**Table 43. Local Temperature Offset**

| Register Address | R/W <sup>1</sup>         | Description                                                                                                                                                          | Power-On Default |
|------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 0x71<br><7:0>    | Read/write<br>Read/write | Local temperature offset.<br>Allows a twos complement offset value to be automatically added to or subtracted from the local temperature reading. LSB value = 0.5°C. | 0x00             |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

**Table 44. Remote 2 Temperature Offset**

| Register Address | R/W <sup>1</sup>         | Description                                                                                                                                                                                                                                                    | Power-On Default |
|------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 0x72<br><7:0>    | Read/write<br>Read/write | Remote 2 temperature offset.<br>Allows a twos complement offset value to be automatically added to or subtracted from the Remote 2 temperature reading. This is to compensate for any inherent system offsets such as PCB trace resistance. LSB value = 0.5°C. | 0x00             |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

**Table 45. Register 0x73—Configuration Register 2 (Power-On Default = 0x00)**

| Bit | Name | R/W <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                               |
|-----|------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | AIN1 | Read/write       | AIN1 = 0, speed of 3-wire fans measured using the TACH output from the fan.<br>AIN1 = 1, Pin 6 is reconfigured to measure the speed of 2-wire fans using an external sensing resistor and coupling capacitor. AIN voltage threshold is set via Configuration Register 4 (Reg. 0x7D). Only relevant in low frequency mode. |
| 1   | AIN2 | Read/write       | AIN2 = 0, speed of 3-wire fans measured using the TACH output from the fan.<br>AIN2 = 1, Pin 7 is reconfigured to measure the speed of 2-wire fans using an external sensing resistor and coupling capacitor. AIN voltage threshold is set via Configuration Register 4 (Reg. 0x7D). Only relevant in low frequency mode. |
| 2   | AIN3 | Read/write       | AIN3 = 0, speed of 3-wire fans measured using the TACH output from the fan.<br>AIN3 = 1, Pin 4 is reconfigured to measure the speed of 2-wire fans using an external sensing resistor and coupling capacitor. AIN voltage threshold is set via Configuration Register 4 (Reg. 0x7D). Only relevant in low frequency mode. |
| 3   | AIN4 | Read/write       | AIN4 = 0, speed of 3-wire fans measured using the TACH output from the fan.<br>AIN4 = 1, Pin 9 is reconfigured to measure the speed of 2-wire fans using an external sensing resistor and coupling capacitor. AIN voltage threshold is set via Configuration Register 4 (Reg. 0x7D). Only relevant in low frequency mode. |
| 4   | AVG  | Read/write       | AVG = 1, averaging on the temperature and voltage measurements is turned off. This allows measurements on each channel to be made much faster.                                                                                                                                                                            |
| 5   | ATTN | Read/write       | ATTN = 1, the ADT7468 removes the attenuators from the 2.5 V, V <sub>CCP</sub> , 5 V, and 12 V inputs. These inputs can be used for other functions such as connecting up external sensors. It is possible to remove attenuators from individual channels using Bits <7:4> of Configuration Register 4 (0x7D).            |
| 6   | CONV | Read/write       | CONV = 1, the ADT7468 is put into a single-channel ADC conversion mode. In this mode, the ADT7468 can be made to read continuously from one input only, for example, Remote 1 temperature. The appropriate ADC channel is selected by writing to Bits <7:5> of TACH1 minimum high byte register (0x55).                   |
|     |      |                  | <b>Bits &lt;7:5&gt; Reg. 0x55</b>                                                                                                                                                                                                                                                                                         |

|     |      |                  | 110 Local temperature                                                                                                                                                                                                                                                                                                     |
|     |      |                  | 111 Remote 2 temperature                                                                                                                                                                                                                                                                                                  |
| 7   | SHDN | Read/write       | SHDN = 1, ADT7468 goes into shutdown mode. All PWM outputs assert low (or high depending on state of INV bit) to switch off all fans. The PWM current duty cycle registers read 0x00 to indicate that the fans are not being driven.                                                                                      |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

**Table 46. Register 0x74—Interrupt Mask Register 1 (Power-On Default <7:0> = 0x00)**

| Bit | Name             | R/W        | Description                                                                                                           |
|-----|------------------|------------|-----------------------------------------------------------------------------------------------------------------------|
| 0   | 2.5V             | Read/write | 2.5 V = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the 2.5 V channel.                       |
| 1   | V <sub>CCP</sub> | Read/write | V <sub>CCP</sub> = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the V <sub>CCP</sub> channel. |
| 2   | V <sub>CC</sub>  | Read/write | V <sub>CC</sub> = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the V <sub>CC</sub> channel.   |
| 3   | 5V               | Read/write | 5 V = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the 5 V channel.                           |
| 4   | RIT              | Read/write | RIT = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the Remote 1 temperature channel.          |
| 5   | LT               | Read/write | LT = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the local temperature channel.              |
| 6   | R2T              | Read/write | R2T = 1, masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the Remote 2 temperature channel.          |
| 7   | OOL              | Read/write | OOL = 1, masks $\overline{\text{SMBALERT}}$ for any out-of-limit condition in Status Register 2.                      |

**Table 47. Register 0x75—Interrupt Mask Register 2 (Power-On Default <7:0> = 0x00)**

| Bit | Name   | R/W        | Description                                                                                                                                                                                                                                                                                                                                                                             |
|-----|--------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 12V/VC | Read/write | When Pin 21 is configured as a 12 V input, 12V/VC = 1 masks $\overline{\text{SMBALERT}}$ for out-of-limit conditions on the 12 V channel. When Pin 21 is programmed as VID5, this bit masks an $\overline{\text{SMBALERT}}$ , if the VID5 VID code bit changes.                                                                                                                         |
| 1   | OVT    | Read only  | OVT = 1, masks $\overline{\text{SMBALERT}}$ for overtemperature $\overline{\text{THERM}}$ conditions.                                                                                                                                                                                                                                                                                   |
| 2   | FAN1   | Read/write | FAN1 = 1, masks $\overline{\text{SMBALERT}}$ for a Fan 1 fault.                                                                                                                                                                                                                                                                                                                         |
| 3   | FAN2   | Read/write | FAN2 = 1, masks $\overline{\text{SMBALERT}}$ for a Fan 2 fault.                                                                                                                                                                                                                                                                                                                         |
| 4   | FAN3   | Read/write | FAN3 = 1, masks $\overline{\text{SMBALERT}}$ for a Fan 3 fault.                                                                                                                                                                                                                                                                                                                         |
| 5   | F4P    | Read/write | If Pin 14 is configured as TACH 4, F4P = 1 masks $\overline{\text{SMBALERT}}$ for a Fan 4 fault.<br>If Pin 14 is configured as $\overline{\text{THERM}}$ , F4P = 1 masks $\overline{\text{SMBALERT}}$ for an exceeded $\overline{\text{THERM}}$ timer limit.<br>If Pin 14 is configured as GPIO, F4P = 1 masks $\overline{\text{SMBALERT}}$ when GPIO is an input and GPIO is asserted. |
| 6   | D1     | Read/write | D1 = 1 masks $\overline{\text{SMBALERT}}$ for a diode open or short on a Remote 1 channel.                                                                                                                                                                                                                                                                                              |
| 7   | D2     | Read/write | D2 = 1 masks $\overline{\text{SMBALERT}}$ for a diode open or short on a Remote 2 channel.                                                                                                                                                                                                                                                                                              |

**Table 48. Register 0x76—Extended Resolution Register 1<sup>1</sup>**

| Bit   | Name             | R/W       | Description                                                                         |
|-------|------------------|-----------|-------------------------------------------------------------------------------------|
| <1:0> | 2.5V             | Read-only | 2.5 V LSBs. Holds the 2 LSBs of the 10-bit 2.5 V measurement.                       |
| <3:2> | V <sub>CCP</sub> | Read-only | V <sub>CCP</sub> LSBs. Holds the 2 LSBs of the 10-bit V <sub>CCP</sub> measurement. |
| <5:4> | V <sub>CC</sub>  | Read-only | V <sub>CC</sub> LSBs. Holds the 2 LSBs of the 10-bit V <sub>CC</sub> measurement.   |
| <7:6> | 5 V              | Read-only | 5 V LSBs. Holds the 2 LSBs of the 10-bit 5 V measurement.                           |

<sup>1</sup>If this register is read, this register and the registers holding the MSB of each reading are frozen until read.

**Table 49. Register 0x77—Extended Resolution Register 2<sup>1</sup>**

| Bit   | Name | R/W       | Description                                                                                 |
|-------|------|-----------|---------------------------------------------------------------------------------------------|
| <1:0> | 12V  | Read-only | 12 V LSBs. Holds the 2 LSBs of the 10-bit 12 V measurement.                                 |
| <3:2> | TDM1 | Read-only | Remote 1 temperature LSBs. Holds the 2 LSBs of the 10-bit Remote 1 temperature measurement. |
| <5:4> | LTMP | Read-only | Local temperature LSBs. Holds the 2 LSBs of the 10-bit local temperature measurement.       |
| <7:6> | TDM2 | Read-only | Remote 2 temperature LSBs. Holds the 2 LSBs of the 10-bit Remote 2 temperature measurement. |

<sup>1</sup>If this register is read, this register and the registers holding the MSB of each reading are frozen until read.

Table 50. Register 0x78—Configuration Register 3 (Power-On Default = 0x00)

| Bit | Name                      | R/W <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|---------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0> | ALERT                     | Read/write       | ALERT = 1, Pin 10 (PWM2/ $\overline{\text{SMBALERT}}$ ) is configured as an $\overline{\text{SMBALERT}}$ interrupt output to indicate out-of-limit error conditions.<br>ALERT = 0, Pin 10 (PWM2/ $\overline{\text{SMBALERT}}$ ) is configured as the PWM2 output.                                                                                                                                                                                                                                                     |
| <1> | $\overline{\text{THERM}}$ | Read/write       | $\overline{\text{THERM}}$ Enable = 1 enables $\overline{\text{THERM}}$ functionality on Pin 20 and Pin 14, if Pin 14 is configured as $\overline{\text{THERM}}$ , determined by Bits 0 and 1 (PIN14FUNC) of Configuration Register 4. When $\overline{\text{THERM}}$ is asserted, if the fans are running and the boost bit is set, the fans run at full speed. Alternatively, $\overline{\text{THERM}}$ can be programmed so that a timer is triggered to time how long $\overline{\text{THERM}}$ has been asserted. |
| <2> | BOOST                     | Read/write       | When $\overline{\text{THERM}}$ is an input and BOOST = 1, assertion of $\overline{\text{THERM}}$ causes all fans to run at the maximum programmed duty cycle for fail-safe cooling.                                                                                                                                                                                                                                                                                                                                   |
| <3> | FAST                      | Read/write       | FAST = 1, enables fast TACH measurements on all channels. This increases the TACH measurement rate from once per second to once every 250 ms (4 ×).                                                                                                                                                                                                                                                                                                                                                                   |
| <4> | DC1                       | Read/write       | DC1 = 1, enables TACH measurements to be continuously made on TACH1. Fans must be driven by dc. Setting this bit prevents pulse stretching, because it is not required for dc-driven motors.                                                                                                                                                                                                                                                                                                                          |
| <5> | DC2                       | Read/write       | DC2 = 1, enables TACH measurements to be continuously made on TACH2. Fans must be driven by dc. Setting this bit prevents pulse stretching, because it is not required for dc-driven motors.                                                                                                                                                                                                                                                                                                                          |
| <6> | DC3                       | Read/write       | DC3 = 1, enables TACH measurements to be continuously made on TACH3. Setting this bit prevents pulse stretching, because it is not required for dc-driven motors.                                                                                                                                                                                                                                                                                                                                                     |
| <7> | DC4                       | Read/write       | DC4 = 1, enables TACH measurements to be continuously made on TACH4. Setting this bit prevents pulse stretching, because it is not required for dc-driven motors.                                                                                                                                                                                                                                                                                                                                                     |

<sup>1</sup> This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

Table 51. Register 0x79— $\overline{\text{THERM}}$  Timer Status Register (Power-On Default = 0x00)

| Bit   | Name          | R/W       | Description                                                                                                                                                                                                                                                                                                                                                           |
|-------|---------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <7:1> | TMR           | Read-only | Times how long $\overline{\text{THERM}}$ input is asserted. These seven bits read zero until the $\overline{\text{THERM}}$ assertion time exceeds 45.52 ms.                                                                                                                                                                                                           |
| <0>   | ASRT/<br>TMRO | Read-only | This bit is set high on the assertion of the $\overline{\text{THERM}}$ input and is cleared on read. If the $\overline{\text{THERM}}$ assertion time exceeds 45.52 ms, this bit is set and becomes the LSB of the 8-bit TMR reading. This allows $\overline{\text{THERM}}$ assertion times from 45.52 ms to 5.82 s to be reported back with a resolution of 22.76 ms. |

Table 52. Register 0x7A— $\overline{\text{THERM}}$  Timer Limit Register (Power-On Default = 0x00)

| Bit   | Name  | R/W        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <7:0> | LIMIT | Read/write | Sets maximum $\overline{\text{THERM}}$ assertion length allowed before an interrupt is generated. This is an 8-bit limit with a resolution of 22.76 ms allowing $\overline{\text{THERM}}$ assertion limits of 45.52 ms to 5.82 s to be programmed. If the $\overline{\text{THERM}}$ assertion time exceeds this limit, Bit 5 (F4P) of Interrupt Status Register 2 (Reg. 0x42) is set. If the limit value is 0x00, then an interrupt is generated immediately on the assertion of the $\overline{\text{THERM}}$ input. |

**Table 53. Register 0x7B—TACH Pulses per Revolution Register (Power-On Default = 0x55)**

| Bit   | Name | R/W        | Description                                                                                                                              |
|-------|------|------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <1:0> | FAN1 | Read/write | Sets number of pulses to be counted when measuring Fan 1 speed. Can be used to determine fan pulses per revolution for unknown fan type. |
|       |      |            | <b>Pulses Counted</b><br>00 = 1<br>01 = 2 (default)<br>10 = 3<br>11 = 4                                                                  |
| <3:2> | FAN2 | Read/write | Sets number of pulses to be counted when measuring Fan 2 speed. Can be used to determine fan pulses per revolution for unknown fan type. |
|       |      |            | <b>Pulses Counted</b><br>00 = 1<br>01 = 2 (default)<br>10 = 3<br>11 = 4                                                                  |
| <5:4> | FAN3 | Read/write | Sets number of pulses to be counted when measuring Fan 3 speed. Can be used to determine fan pulses per revolution for unknown fan type. |
|       |      |            | <b>Pulses Counted</b><br>00 = 1<br>01 = 2 (default)<br>10 = 3<br>11 = 4                                                                  |
| <7:6> | FAN4 | Read/write | Sets number of pulses to be counted when measuring Fan 4 speed. Can be used to determine fan pulses per revolution for unknown fan type. |
|       |      |            | <b>Pulses Counted</b><br>00 = 1<br>01 = 2 (default)<br>10 = 3<br>11 = 4                                                                  |

**Table 54. Register 0x7C—Configuration Register 5 (Power-On Default = 0x00)**

| Bit   | Name  | R/W <sup>1</sup> | Description                                                                                                                                                                                                                                         |
|-------|-------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0>   | 2sC   | Read/write       | 2sC = 1, sets the temperature range to twos complement temperature range.<br>2sC = 0, changes the temperature range to Offset 64. When this bit is changed, the ADT7468 interprets all relevant temperature register values as defined by this bit. |
| <1>   | HF/LF |                  | Sets the PWM drive frequency to high frequency mode (0) or low frequency mode (1).                                                                                                                                                                  |
| <2>   | GPIOD |                  | GPIO direction. When GPIO function is enabled, this determines whether the GPIO is an input (0) or an output (1).                                                                                                                                   |
| <3>   | GPIOP |                  | GPIO polarity. When the GPIO function is enabled and is programmed as an output, this bit determines whether the GPIO is active low (0) or high (1).                                                                                                |
| <4:7> | RES   |                  | Unused.                                                                                                                                                                                                                                             |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

# ADT7468

**Table 55. Register 0x7D—Configuration Register 4 (Power-On Default = 0x00)**

| Bit   | Name                  | R/W <sup>1</sup> | Description                                                                                                                                                                             |
|-------|-----------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1:0> | PIN14FUNC             | Read/write       | These bits set the functionality of Pin 14:<br>00 = TACH4 (default)<br>01 = Bidirectional $\overline{\text{THERM}}$<br>10 = $\overline{\text{SMBALERT}}$<br>11 = GPIO                   |
| <3:2> | AINL                  | Read/write       | These two bits define the input threshold for 2-wire fan speed measurements (low frequency mode only):<br>00 = $\pm 20$ mV<br>01 = $\pm 40$ mV<br>10 = $\pm 80$ mV<br>11 = $\pm 130$ mV |
| <4>   | BpAtt2.5V             |                  | Bypass 2.5 V attenuator. When set, the measurement scale for this channel changes from 0 V (0x00) to 2.2965 V (0xFF).                                                                   |
| <5>   | BpAttV <sub>CCP</sub> |                  | Bypass V <sub>CCP</sub> attenuator. When set, the measurement scale for this channel changes from 0 V (0x00) to 2.2965 V (0xFF).                                                        |
| <6>   | BpAtt5V               |                  | Bypass 5 V attenuator. When set, the measurement scale for this channel changes from 0 V (0x00) to 2.2965 V (0xFF).                                                                     |
| <7>   | BpAtt12V              |                  | Bypass 12 V attenuator. When set, the measurement scale for this channel changes from 0 V (0x00) to 2.2965 V (0xFF).                                                                    |

<sup>1</sup>This register becomes read-only when the Configuration Register 1 lock bit is set to 1. Any further attempts to write to this register have no effect.

**Table 56. Register 0x7E—Manufacturer's Test Register 1 (Power-On Default = 0x00)**

| Bit   | Name     | R/W       | Description                                                                                                                                        |
|-------|----------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <7:0> | Reserved | Read-only | Manufacturer's test register. These bits are reserved for manufacturer's test purposes and should <i>not</i> be written to under normal operation. |

**Table 57. Register 0x7F—Manufacturer's Test Register 2 (Power-On Default = 0x00)**

| Bit   | Name     | R/W       | Description                                                                                                                                        |
|-------|----------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <7:0> | Reserved | Read-only | Manufacturer's test register. These bits are reserved for manufacturer's test purposes and should <i>not</i> be written to under normal operation. |
