Vertical and Planar Hall-Effect Switches

FEATURES AND BENEFITS

- ASIL A functional safety compliance
- Planar and vertical Hall-effect sensor ICs
- 3.3 to 24 V operation
- Automotive-grade ruggedness and fault tolerance
  - □ Extended AEC-Q100 qualification
  - □ Internal protection circuits enable 40 V load dump compliance
  - □ Reverse-battery protection
  - □ Output short-circuit and overvoltage protection
  - □ Operation from –40°C to 175°C junction temperature
  - □ High EMC immunity
- Omnipolar and unipolar switch threshold options
- Choice of output polarity
- Open-drain output
- Solid-state reliability

(suffix LH)

3-pin SIP (suffix UA)

DESCRIPTION

The APS11000 and APS11060 families of Hall-effect switches are AEC-Q100 qualified for 24 V automotive applications and compliant with ISO 26262:2011 ASIL A. These sensors are temperature-stable and suited for operation over extended junction temperature ranges up to 175°C. The APS11000 and APS11060 families are available in several different magnetic sensitivities and polarities to offer flexible options for system design. They are available in active high and active low variants for ease of integration into electronic subsystems.

The APS11000 features a Hall-effect element that is sensitive to magnetic flux perpendicular to the face of the IC package. The APS11060 features a vertical Hall-effect sensing element sensitive to magnetic flux parallel to the face of the IC package.

TYPICAL APPLICATIONS

- Gear shift selectors and driver controls (PRNDL)
- Human-machine interfaces (HMI) and driver controls
- Open/close sensor for LCD screens/doors/lids/trunks
- Clutch/brake position sensor
- Magnetically actuated lighting
- Wiper home/end position sensor
- End of travel and index sensors

Figure 1: Functional Block Diagram

DESCRIPTION (continued)
The devices include on-board reverse-battery and overvoltage protection for operating directly from an automobile battery, as well as protection from shorts to ground by limiting the output current until the short is removed. The device is especially suited for operation from unregulated supplies.

Two package styles provide a choice of through-hole or surface mounting. Package type LH is a modified 3-pin SOT23W surface mount package, while package type UA is a 3-pin ultra-mini SIP for through-hole mounting. Both packages are lead (Pb) free, with 100% matte-tin-plated leadframes.

FUNCTIONAL DESCRIPTION

Power-On Behavior

Device power-on begins when the supply voltage reaches V_{CC}(min). During the power-on time, t_{PO}, the device output is off with the exception of the leakage current, $I_{OUTOFF(PO)}$. Use of a large pull-up resistor, $R_{PULL-UP}$ (see Figure 6), can influence the Power-On State (POS) voltage level on the output pin during t_{ON}. The output voltage level during the POS is a function of the pull-up resistor and pull-up voltage. The level can be determined by subtracting the voltage drop created by $R_{PULL-UP}$ and $I_{OUTOFF(PO)}$ from the pull-up voltage. To retain a power-on output voltage level above $V_{PULL-UP}/2$, a pull-up resistor less than or equal to 20 kΩ is recommended. After power-on is complete and the power-on time has elapsed, the device output will correspond with the applied magnetic field for $B > B_{OP}$ and $B < B_{RP}$. Powering-on the device in the hysteresis range (less than B_{OP} and higher than B_{RP}) will cause the device output to remain off. A valid output state is attained after the first excursion beyond B_{OP} or B_{RP}.

Undervoltage Lockout Operation

The APS11000 and APS11060 have an internal diagnostic to check the voltage supply (an undervoltage lockout regulator). When the supply voltage falls below the undervoltage lockout voltage threshold, $V_{CC(UV)EN}$, the device enters reset, where the output state returns to the Power-On State (POS) until V_{CC} is increased to $V_{CC(UV)DIS}$. Once the $V_{CC(UV)DIS}$ threshold is reached, the power-on sequence begins and the output will correspond with the applied magnetic field for $B > B_{OP}$ and $B < B_{RP}$ after t_{POR} has elapsed. In the case the supply voltage does not return to these operational levels, or if the applied magnetic field is within the hysteresis range, the output will remain in the power-on state. See Figure 4 for an example of the undervoltage lockout behavior.

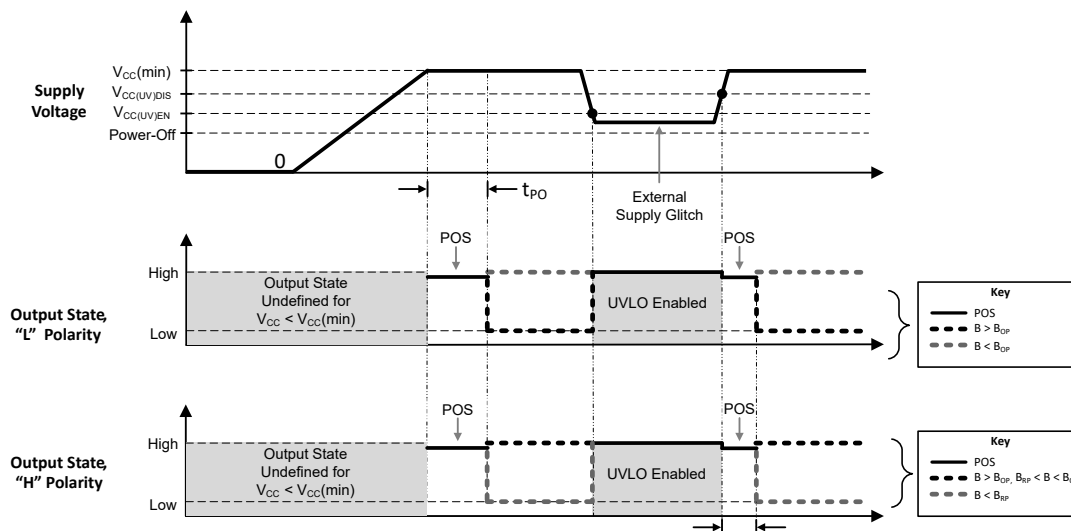

Figure 4: Power-On and Undervoltage Lockout Behavior

Functional Safety

The APS11000 and APS11060 were designed *A²-SIL™* in accordance with the international standard for automotive functional safety, ISO 26262:2011. These products achieve an ASIL (Automotive Safety Integrity Level) rating of ASIL A according to the standard. The APS11000 and APS11060 are both classified as a SEooC (Safety Element out of Context) and can be easily integrated into safety-critical systems requiring higher ASIL ratings that incorporate external diagnostics or use measures such as redundancy. Safety documentation will be provided to support and guide the integration process. For further information, contact your local FAE for A²-SIL™ documentation: www.allegromicro.com/ASIL.

Operation

The APS11000 and APS11060 are integrated Hall-effect sensor ICs with an open-drain output. Table 1 offers a guide for selecting the output polarity configuration, further explained in the configuration sections below. The open-drain output is an NMOS transistor that actuates in response to a magnetic field. The direction of the applied magnetic field is perpendicular to the branded face for the APS11000, and parallel with the branded face for the APS11060; see Figure 5 for an illustration. The devices are offered in two packages: the UA package, a 3-pin through-hole mounting configuration, or in the LH package, a 3-pin surface-mount configuration. See the Selection Guide for a complete list of available options.

Configurations xSL and xSH. The unipolar output of these devices is actuated when a south-polarity magnetic field perpendicular to the Hall element exceeds the operate point threshold, B_{OPS}. When B_{OPS} is exceeded, the xSL output turns on (goes low). The xSH is complementary, in that for this device the output turns off (goes high) when B_{OPS} is exceeded. When the magnetic field is removed or reduced below the release point, B_{RPS}, the device outputs return to their original state—off for the xSL and on for the xSH. See Figure 3 for unipolar south switching behavior.

Configurations xNL and xNH. The unipolar output of these devices is actuated when a north-polarity magnetic field perpendicular to the Hall element exceeds the operate point threshold, B_{OPN}. When B_{OPN} is exceeded, the xNL output turns on (goes low). The xNH is complementary, in that for this device the output turns off (goes high) when B_{OPN} is exceeded. When the magnetic field is removed or reduced below the release point, B_{RPN}, the device outputs return to their original state—off for the xNL and on for the xNH. See Figure 3 for unipolar north switching behavior.

Table 1: Switch Polarity Configuration Options

Part Number Suffix	Operating Mode	Output State for $B > B_{OP}$	Output State for $B = 0$ G	Power-On State, $t < t_{PO}$
xSL	Unipolar South	Low	High	High
xSH	Unipolar South	High	Low	High
xNL	Unipolar North	Low	High	High
xNH	Unipolar North	High	Low	High
xPL	Omnipolar	Low	High	High
xPH	Omnipolar	High	Low	High

Configurations xPL and xPH. The omnipolar operation of these devices allows actuation with either a north or a south polarity field. The xPL operates using the standard output polarity convention. Fields exceeding the operating points, B_{OPS} or B_{OPN}, will turn the output on (low). When the magnetic field is removed or reduced below the release point, B_{RPN} or B_{RPS}, the device output turns off (goes high). The xPH is complementary, in that for the device, a north or south polarity field exceeding the operate points, B_{OPS} or B_{OPN}, will turn the output off (high). Removal of the field, or reduction below the release point threshold, B_{RPS} or B_{RPN}, will turn the output on (low). See Figure 3 for omnipolar switching behavior.

After turn-on, the output transistor is capable of sinking current up to the short circuit current limit, I_{OM}, which is a minimum of 15 mA. The difference in the magnetic operate and release points is the hysteresis, B_{HYS}, of the device. This built-in hysteresis allows clean switching of the output even in the presence of external mechanical vibration and electrical noise.

Figure 5: Magnetic Sensing Orientations

Applications

It is strongly recommended that an external bypass capacitor be connected (in close proximity to the Hall element) between the supply and ground of the device to guarantee correct performance under harsh environmental conditions and to reduce noise from internal circuitry. As is shown in Figure 6: Typical and Enhanced Protection Application Circuits, a 0.1 µF capacitor is required.
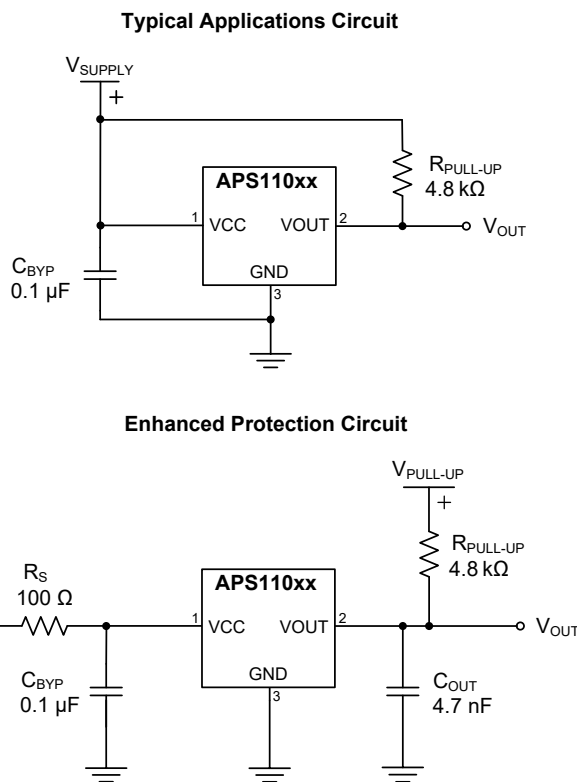

In applications where the APS11000 or APS11060 receives its power from an unregulated source such as a car battery, or where greater immunity is required, additional measures may be employed. Specifications for such transients will vary, so protection circuit design should be optimized for each application. For example, the circuit shown in Figure 6 includes an optional series resistor and output capacitor which improves performance during Powered ESD testing (ISO 10605) and Bulk Current Injection testing (ISO 11452-4).

Vertical Hall-Effect Sensor Linear Tools

System design and magnetic sensor evaluation often require an in-depth look at the overall strength and profile generated by a magnetic field input. To aid in this evaluation, Allegro MicroSystems, LLC provides a high-accuracy linear output tool capable of reporting the nonperpendicular magnetic field by means of an vertical Hall-effect sensor IC equipped with a calibrated analog output. For further information, contact your local Allegro field applications engineer or sales representative.

Typical Applications Circuit

Enhanced Protection Circuit

Protection Application Circuits**

Recommended $R_{PULL-UP} \leq 20$ kΩ.
See Power-On Behavior section.

CHOPPER STABILIZATION

A limiting factor for switchpoint accuracy when using Hall-effect technology is the small signal voltage developed across the Hall plate. This voltage is proportionally small relative to the offset that can be produced at the output of the Hall sensor. This makes it difficult to process the signal and maintain an accurate, reliable output over the specified temperature and voltage range. Chopper stabilization is a proven approach used to minimize Hall offset.

The technique, dynamic quadrature offset cancellation, removes key sources of the output drift induced by temperature and package stress. This offset reduction technique is based on a signal modulation-demodulation process. Figure 7: Model of Chopper Stabilization Circuit (Dynamic Offset Cancellation) illustrates how it is implemented.

The undesired offset signal is separated from the magnetically induced signal in the frequency domain through modulation. The subsequent demodulation acts as a modulation process for the offset causing the magnetically induced signal to recover its original spectrum at baseband while the DC offset becomes a high-frequency signal. Then, using a low-pass filter, the signal passes while the modulated DC offset is suppressed. Allegro's innovative chopper-stabilization technique uses a high-frequency clock.

The high-frequency operation allows a greater sampling rate that produces higher accuracy, reduced jitter, and faster signal processing. Additionally, filtering is more effective and results in a lower noise analog signal at the sensor output. Devices such as the APS11000 and APS11060 that use this approach have an extremely stable quiescent Hall output voltage, are immune to thermal stress, and have precise recoverability after temperature cycling. This technique is made possible through the use of a BiCMOS process which allows the use of low offset and low noise amplifiers in combination with high-density logic and sample-and-hold circuits.

**Figure 7: Model of Chopper Stabilization Circuit
(Dynamic Offset Cancellation)**

POWER DERATING

The device must be operated below the maximum junction temperature, T_J(max). Reliable operation may require derating supplied power and/or improving the heat dissipation properties of the application.

Thermal Resistance, $R_{\theta JA}$ (junction to ambient), is a figure of merit summarizing the ability of the application and the device to dissipate heat from the junction (die), through all paths to ambient air. $R_{\theta JA}$ is dominated by the Effective Thermal Conductivity, K, of the printed circuit board which includes adjacent devices and board layout. Thermal resistance from the die junction to case, $R_{\theta JC}$, is a relatively small component of $R_{\theta JA}$. Ambient air temperature, T_A, and air motion are significant external factors in determining a reliable thermal operating point.

The following three equations can be used to determine operation points for given power and thermal conditions:

$$P_D = V_{IN} \times I_{IN} \ (1)$$

$$\Delta T = P_D \times R_{\theta JA} \ (2)$$

$$T_J = T_A + \Delta T \ (3)$$

Determining Junction Temperature

For example, given common conditions: T_A = 25°C, V_{CC} = 12 V, I_{CC} = 2.5 mA, $V_{OUT(SAT)}$ = 100 mV, I_{OUT} = 5 mA, and $R_{\theta JA}$ = 165°C/W, then:

$$P_D = (V_{CC} \times I_{CC}) + (V_{OUT} \times I_{OUT}) =$$

$$(12 \ V \times 2.5 \ mA) + (100 \ mV \times 5 \ mA) =$$

$$30 \ mW + 0.5 \ mW = 30.5 \ mW$$

$$\Delta T = P_D \times R_{\theta JA} = 30.5 \ mW \times 165°C/W = 5°C$$

$$T_J = T_A + \Delta T = 25°C + 5°C = 30°C$$

Determining Maximum V_{CC}

For a given ambient temperature (T_A), the maximum allowable power dissipation as a function of V_{CC} can be calculated. P_D(max), represents the maximum allowable power level without exceeding T_J(max), at a selected $R_{\theta JA}$ and T_A.

Example: V_{CC} estimation using the conditions $R_{\theta JA}$ = 228°C/W, T_A(max) = 150°C, T_J(max) = 175°C, V_{CC}(max) = 24 V, I_{CC}(max) = 5 mA, V_{OUT} = 500 mV, and I_{OUT} = 20 mA (output on), calculate the maximum allowable power level, P_D(max), first using equation 3:

$$\Delta T(max) = T_J(max) - T_A = 175°C - 150°C = 25°C$$

This provides the allowable increase to T_J resulting from internal power dissipation. Then, using equation 2 first for the output as shown below:

$$P_{D(VOUT)} = V_{OUT} \times I_{OUT} = 500 \ mV \times 20 \ mA = 10 \ mW$$

Then, for the V_{CC} supply:

$$P_{D(VCC)} = V_{CC} \times I_{CC} = 24 \ V \times 5 \ mA = 120 \ mW$$

Combine the power dissipated by the device pins:

$$P_D \ (total) = (P_{D(VOUT)} + P_{D(VCC)})$$

$$P_D \ (total) = (10 \ mW + 120 \ mW) = 130 \ mW$$

Next, solve for the maximum allowable V_{CC} for the given conditions using equation 1:

$$V_{CC}(est) = P_D(total) \div (I_{CC} + I_{OUT})$$

$$130 \ mW \div (5 \ mA + 20 \ mA)$$

$$V_{CC}(est) = 130 \ mW \div 25 \ mA = 5.2 \ V$$

The result indicates that, at T_A, the application and device can dissipate adequate amounts of heat at voltages $\leq V_{CC}$ (est).

If the application requires $V_{CC} > V_{CC}$(est) then $R_{\theta JA}$ must by improved. This can be accomplished by adjusting the layout, PCB materials, or by controlling the ambient temperature.

Determining Maximum T_A

In cases where the V_{CC} (max) level is known, and the system designer would like to determine the maximum allowable ambient temperature, T_A (max), the calculations can be reversed.

For example, in a worst-case scenario with conditions V_{CC} (max) = 24 V, I_{CC} (max) = 5 mA, I_{OUT} (max) = 20 mA, and $R_{\theta JA}$ = 228°C/W, for the LH package using equation 1, the largest possible amount of dissipated power is:

$$P_D = V_{IN} \times I_{IN}$$
$$P_D = 24 \ V \times (I_{CC} + I_{OUT})$$

$$P_D = 24 \ V \times (5 \ mA + 20 \ mA) = 600 \ mW$$

Then, by rearranging equation 3:

$$T_A \ (max) = T_J \ (max) - \Delta T$$

$$T_A \ (max) = 175°C - (600 \ mW \times 228°C/W)$$

$$T_A \ (max) = 175°C - 136.8°C = 38.2°C$$

Finally, note that the T_A (max) rating of the device is 150°C and performance is not guaranteed above this temperature for any power level.
