

# 10-Bit, 80Msps, Single 3.0V, Low-Power ADC with Internal Reference

**MAX1448**

## General Description

The MAX1448 3V, 10-bit analog-to-digital converter (ADC) features a fully differential input, a pipelined 10-stage ADC architecture with wideband track-and-hold (T/H), and digital error correction incorporating a fully differential signal path. The ADC is optimized for low-power, high dynamic performance in imaging and digital communications applications. The converter operates from a single 2.7V to 3.6V supply, consuming only 120mW while delivering a 59dB (typ) signal-to-noise ratio (SNR) at a 20MHz input frequency. The fully differential input stage has a -3dB 400MHz bandwidth and may be operated with single-ended inputs. In addition to low operating power, the MAX1448 features a 5μA power-down mode for idle periods.

An internal 2.048V precision bandgap reference is used to set the ADC full-scale range. A flexible reference structure allows the user to supply a buffered, direct, or externally derived reference for applications requiring increased accuracy or a different input voltage range.

Lower speed, pin-compatible versions of the MAX1448 are also available. Refer to the MAX1444 data sheet for a 40Msps version and to the MAX1446 data sheet for a 60Msps version.

The MAX1448 has parallel, offset binary, CMOS-compatible three-state outputs that can be operated from 1.7V to 3.6V to allow flexible interfacing. The device is available in a 5mm x 5mm 32-pin TQFP package and is specified over the extended industrial (-40°C to +85°C) temperature range.

## Applications

Ultrasound Imaging  
CCD Imaging  
Baseband and IF Digitization  
Digital Set-Top Boxes  
Video Digitizing Applications

## Features

- ◆ Single 3.0V Operation
- ◆ Excellent Dynamic Performance
  - 59dB SNR at  $f_{IN} = 20\text{MHz}$
  - 74dBc SFDR at  $f_{IN} = 20\text{MHz}$
- ◆ Low Power
  - 40mA (Normal Operation)
  - 5μA (Shutdown Mode)
- ◆ Fully Differential Analog Input
- ◆ Wide 2V<sub>p-p</sub> Differential Input Voltage Range
- ◆ 400MHz -3dB Input Bandwidth
- ◆ On-Chip 2.048V Precision Bandgap Reference
- ◆ CMOS-Compatible Three-State Outputs
- ◆ 32-Pin TQFP Package
- ◆ Evaluation Kit Available (MAX1448 EV Kit)

## Ordering Information

| PART       | TEMP RANGE     | PIN-PACKAGE |
|------------|----------------|-------------|
| MAX1448EHJ | -40°C to +85°C | 32 TQFP     |

## Functional Diagram

Pin Configuration appears at end of data sheet.

# 10-Bit, 80Msps, Single 3.0V, Low-Power ADC with Internal Reference

## ABSOLUTE MAXIMUM RATINGS

V<sub>DD</sub>, OV<sub>DD</sub> to GND .....-0.3V to +3.6V  
 OGND to GND .....-0.3V to +0.3V  
 IN+, IN- to GND .....-0.3V to V<sub>DD</sub>  
 REFIN, REFOUT, REFP,  
 REFN, and COM to GND .....-0.3V to (V<sub>DD</sub> + 0.3V)  
 OE, PD, CLK to GND .....-0.3V to (V<sub>DD</sub> + 0.3V)  
 D9–D0 to GND .....-0.3V to (OV<sub>DD</sub> + 0.3V)

Continuous Power Dissipation (T<sub>A</sub> = +70°C)  
 32-Pin TQFP (derate 18.7mW/°C above +70°C) .....1495.3mW  
 Operating Temperature Range .....-40°C to +85°C  
 Junction Temperature .....+150°C  
 Storage Temperature Range .....-60°C to +150°C  
 Lead Temperature (soldering, 10s) .....+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

(V<sub>DD</sub> = 3.0V, OV<sub>DD</sub> = 2V, 0.1μF and 1μF capacitors from REFP, REFN, and COM to GND, V<sub>REFIN</sub> = 2.048V, REFOUT connected to REFIN through a 10kΩ resistor, V<sub>IN</sub> = 2V<sub>P-P</sub> (differential with respect to COM), C<sub>L</sub> = 10pF at digital outputs, f<sub>CLK</sub> = 83.3MHz, T<sub>A</sub> = T<sub>MIN</sub> to T<sub>MAX</sub>, unless otherwise noted. ≥ +25°C guaranteed by production test, < +25°C guaranteed by design and characterization; typical values are at T<sub>A</sub> = +25°C.)

## ELECTRICAL CHARACTERISTICS (continued)

( $V_{DD} = 3.0V$ ,  $OV_{DD} = 2V$ ,  $0.1\mu F$  and  $1\mu F$  capacitors from REFP, REFN, and COM to GND,  $V_{REFIN} = 2.048V$ , REFOUT connected to REFIN through a  $10k\Omega$  resistor,  $V_{IN} = 2V_{P-P}$  (differential with respect to COM),  $C_L = 10pF$  at digital outputs,  $f_{CLK} = 83.3MHz$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted.  $\geq +25^\circ C$  guaranteed by production test,  $< +25^\circ C$  guaranteed by design and characterization; typical values are at  $T_A = +25^\circ C$ .)

## Detailed Description

The MAX1448 uses a 10-stage, fully differential, pipelined architecture (Figure 1) that allows for high-speed conversion while minimizing power consumption. Each sample moves through a pipeline stage every half clock-cycle. Counting the delay through the output latch, the clock-cycle latency is 5.5.

A 1.5-bit (2-comparator) flash ADC converts the held input voltage into a digital code. The following digital-to-analog converter (DAC) converts the digitized result back into an analog voltage, which is then subtracted from the original held input signal. The resulting error signal is then multiplied by two, and the product is passed along to the next pipeline stage where the process is repeated. Each stage provides a 1-bit resolution. Digital error correction compensates for ADC comparator offsets in each pipeline stage and ensures no missing codes.

## Input Track-and-Hold Circuit

Figure 2 displays a simplified functional diagram of the input track-and-hold (T/H) circuit in both track and hold mode. In track mode, switches S1, S2a, S2b, S4a, S4b, S5a, and S5b are closed. The fully differential circuit samples the input signal onto the two capacitors (C2a and C2b) through S4a and S4b. S2a and S2b set the common mode for the amplifier input and open simulta-

neously with S1, sampling the input waveform. S4a and S4b are then opened before S3a and S3b connect capacitors C1a and C1b to the amplifier output, and S4c is closed. The resulting differential voltage is held on C2a and C2b. The amplifier is used to charge C1a and C1b to the same values originally held on C2a and C2b. This value is then presented to the first-stage quantizer and isolates the pipeline from the fast-changing input. The wide-input-bandwidth T/H amplifier allows the MAX1448 to track and sample/hold analog inputs of high frequencies beyond Nyquist. Analog inputs (IN+ and IN-) can be driven either differentially or single-ended. It is recommended to match the impedance of IN+ and IN- and set the common-mode voltage to midsupply ( $V_{DD}/2$ ) for optimum performance.

## Analog Input and Reference Configuration

The MAX1448 full-scale range is determined by the internally generated voltage difference between REFP ( $V_{DD}/2 + V_{REFIN}/4$ ) and REFN ( $V_{DD}/2 - V_{REFIN}/4$ ). The ADC's full-scale range is user-adjustable through the REF pin, which provides a high input impedance for this purpose. REFOUT, REFP, COM ( $V_{DD}/2$ ), and REFN are internally buffered, low-impedance outputs.

Figure 1. Pipelined Architecture—Stage Blocks

Figure 2. Internal Track-and-Hold Circuit

# 10-Bit, 80Msps, Single 3.0V, Low-Power ADC with Internal Reference

The MAX1448 provides three modes of reference operation:

- Internal reference mode
- Buffered external reference mode
- Unbuffered external reference mode

In internal reference mode, the internal reference output (REFOUT) can be tied to the REFIN pin through a resistor (e.g., 10k $\Omega$ ) or resistor-divider if an application requires a reduced full-scale range. For stability purposes, it is recommended to bypass REFIN with a >10nF capacitor to GND.

In buffered external reference mode, the reference voltage levels can be adjusted externally by applying a stable and accurate voltage at REFIN. In this mode, REFOUT may be left open or connected to REFIN through a >10k $\Omega$  resistor.

In unbuffered external reference mode, REFIN is connected to GND, thereby deactivating the on-chip buffers of REFP, COM, and REFN. With their buffers shut down, these pins become high impedance and can be driven by external reference sources.

## Clock Input (CLK)

The MAX1448 CLK input accepts CMOS-compatible clock signals. Since the interstage conversion of the device depends on the repeatability of the rising and falling edges of the external clock, use a clock with low jitter and fast rise and fall times (<2ns). In particular, sampling occurs on the falling edge of the clock signal, mandating this edge to provide lowest possible jitter. Any significant aperture jitter would limit the SNR performance of the ADC as follows:

$$\text{SNR} = 20 \times \log \left( \frac{1}{2 \times \pi \times f_{\text{IN}} \times t_{\text{AJ}}} \right)$$

where  $f_{\text{IN}}$  represents the analog input frequency, and  $t_{\text{AJ}}$  is the time of the aperture jitter.

Clock jitter is especially critical for undersampling applications. The clock input should always be considered as an analog input and routed away from any analog input or other digital signal lines.

The MAX1448 clock input operates with a voltage threshold set to  $V_{\text{DD}}/2$ . Clock inputs with a duty cycle other than 50% must meet the specifications for high and low periods as stated in the *Electrical Characteristics*. See Figures 3a, 3b, 4a, and 4b for the relationship between spurious-free dynamic range (SFDR), signal-to-noise ratio (SNR), total harmonic distortion (THD), or signal-to-noise plus distortion (SINAD) versus duty cycle.

## Output Enable ( $\overline{\text{OE}}$ ), Power Down (PD), and Output Data (D0–D9)

All data outputs, D0 (LSB) through D9 (MSB), are TTL/CMOS-logic compatible. There is a 5.5 clock-cycle latency between any particular sample and its valid output data. The output coding is straight offset binary (Table 1). With  $\overline{\text{OE}}$  and PD high, the digital outputs enter a high-impedance state. If  $\overline{\text{OE}}$  is held low with PD high, the outputs are latched at the last value prior to the power down.

The capacitive load on the digital outputs D0–D9 should be kept as low as possible (<15pF) to avoid large digital currents that could feed back into the analog portion of the MAX1448, degrading its dynamic performance. Using buffers on the ADC's digital outputs can further isolate the digital outputs from heavy capacitive loads. To further improve the MAX1448's dynamic performance, small series resistors (e.g., 100 $\Omega$ ) may be added to the digital output paths, close to the ADC.

Figure 5 displays the timing relationship between output enable and data output valid as well as power-down/wake-up and data output valid.

**Table 1. MAX1448 Output Code for Differential Inputs**

| DIFFERENTIAL INPUT VOLTAGE*      | DIFFERENTIAL INPUT         | STRAIGHT OFFSET BINARY |

## System Timing Requirements

Figure 6 shows the relationship between the clock input, analog input, and data output. The MAX1448 samples at the falling edge of the input clock. Output data is valid on the rising edge of the input clock. The output data has an internal latency of 5.5 clock cycles. Figure 6 also shows the relationship between the input clock parameters and the valid output data.

## Applications Information

Figure 7 shows a typical application circuit containing a single-ended to differential converter. The internal reference provides a  $V_{DD}/2$  output voltage for level shifting purposes. The input is buffered and then split to a voltage follower and inverter. A lowpass filter follows the op amps to suppress some of the wideband noise associated with high-speed op amps. The user may select the  $R_{ISO}$  and  $C_{IN}$  values to optimize the filter performance to suit a particular application. For the application in Figure 7, an  $R_{ISO}$  of  $50\Omega$  is placed before the capacitive load to prevent ringing and oscillation. The  $22pF$   $C_{IN}$  capacitor acts as a small bypassing capacitor.

## Using Transformer Coupling

An RF transformer (Figure 8) provides an excellent solution for converting a single-ended source signal to a fully differential signal, required by the MAX1448 for optimum performance. Connecting the transformer's center tap to COM provides a  $V_{DD}/2$  DC level shift to the input. Although a 1:1 transformer is shown, a step-up transformer may be selected to reduce the drive requirements. A reduced signal swing from the input driver, such as an op amp, may also improve the overall distortion.

In general, the MAX1448 provides better SFDR and THD with fully differential input signals than single-ended drive, especially for very high input frequencies. In differential input mode, even-order harmonics are lower since both inputs ( $IN+$ ,  $IN-$ ) are balanced, and each of the inputs only requires half the signal swing compared to single-ended mode.

## Single-Ended AC-Coupled Input Signal

Figure 9 shows an AC-coupled, single-ended application. The MAX4108 op amp provides high speed, high bandwidth, low noise, and low distortion to maintain the integrity of the input signal.

# MAX1448

Multiple-converter systems based on the MAX1448 are well suited for use with a common reference voltage. The REFIN pin of those converters can be connected directly to an external reference source. A precision bandgap reference like the MAX6062 generates an external DC level of 2.048V (Figure 10), and exhibits a noise voltage density of 150nV/ $\sqrt{\text{Hz}}$ . Its output passes through a 1-pole lowpass filter (with 10Hz cutoff fre-

MAX1448

Figure 11. Unbuffered External Reference Drives Up to 32 ADCs

## Unbuffered External Reference Drives Multiple ADCs

Connecting each REFOUT to analog ground disables the internal reference of each device, allowing the internal reference ladders to be driven directly by a set of external reference sources. Followed by a 10Hz lowpass filter and precision voltage-divider (Figure 11), the MAX6066 generates a DC level of 2.500V. The buffered outputs of this divider are set to 2.0V, 1.5V, and 1.0V, with an accuracy that depends on the tolerance of the divider resistors. The three voltages are buffered by the MAX4252, which provides low noise and low DC offset. The individual voltage followers are connected to 10Hz lowpass filters, which filter both the reference voltage

and amplifier noise to a level of  $3\text{nV}/\sqrt{\text{Hz}}$ . The 2.0V and 1.0V reference voltages set the differential full-scale range of the associated ADCs at 2V<sub>P-P</sub>. The 2.0V and 1.0V buffers drive the ADC's internal ladder resistances between them. Note that the common power supply for all active components removes any concern regarding power-supply sequencing when powering up or down. With the outputs of the MAX4252 matching better than 0.1%, the buffers and subsequent lowpass filters can be replicated to support as many as 32 ADCs. For applications that require more than 32 matched ADCs, a voltage reference and divider string common to all converters is highly recommended.

# 10-Bit, 80Msps, Single 3.0V, Low-Power ADC with Internal Reference

## Grounding, Bypassing, and Board Layout

The MAX1448 requires high-speed board layout design techniques. Locate all bypass capacitors as close to the device as possible, preferably on the same side as the ADC, using surface-mount devices for minimum inductance. Bypass  $V_{DD}$ , REFP, REFN, and COM with two parallel 0.1 $\mu$ F ceramic capacitors and a 2.2 $\mu$ F bipolar capacitor to GND. Follow the same rules to bypass the digital supply ( $OV_{DD}$ ) to OGND. Multilayer boards with separated ground and power planes produce the highest level of signal integrity. Consider using a split ground plane arranged to match the physical location of the analog ground (GND) and the digital output driver ground (OGND) on the ADC's package.

The two ground planes should be joined at a single point so that the noisy digital ground currents do not interfere with the analog ground plane. The ideal location of this connection can be determined experimentally at a point along the gap between the two ground planes that produces optimum results. Make this connection with a low-value, surface-mount resistor (1 $\Omega$  to 5 $\Omega$ ), a ferrite bead, or a direct short. Alternatively, all ground pins could share the same ground plane if the ground plane is sufficiently isolated from any noisy, digital systems ground plane (e.g., downstream output buffer or DSP ground plane). Route high-speed digital signal traces away from sensitive analog traces. Keep all signal lines short and free of 90° turns.

## Static Parameter Definitions

### Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best straight-line fit or a line drawn between the endpoints of the transfer function once offset and gain errors have been nullified. The MAX1448's static linearity parameters are measured using the best straight-line fit method.

### Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1LSB. A DNL error specification of less than 1LSB guarantees no missing codes and a monotonic transfer function.

## Dynamic Parameter Definitions

### Aperture Jitter

Figure 12 depicts the aperture jitter ( $t_{AJ}$ ), which is the sample-to-sample variation in the aperture delay.

### Aperture Delay

Aperture delay ( $t_{AD}$ ) is the time defined between the falling edge of the sampling clock and the instant when an actual sample is taken (Figure 12).

### Signal-to-Noise Ratio (SNR)

For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum A/D noise is caused by quantization error only and results directly from the ADC's resolution (N bits):

$$SNR_{(MAX)} = (6.02 \times N + 1.76)dB$$

In reality, there are other noise sources besides quantization noise: thermal noise, reference noise, clock jitter, etc. SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

### Signal-to-Noise Plus Distortion (SINAD)

SINAD is computed by taking the ratio of the RMS signal to all spectral components minus the fundamental and the DC offset.

### Effective Number of Bits (ENOB)

ENOB specifies the dynamic performance of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quantization noise only. ENOB is computed from:

$$ENOB = \frac{(SINAD - 1.76)}{6.02}$$

### Total Harmonic Distortion (THD)

THD is typically the ratio of the RMS sum of the input signal's first five harmonics to the fundamental itself. This is expressed as:

$$THD = 20 \times \log \left( \frac{\sqrt{(V_2^2 + V_3^2 + V_4^2 + V_5^2)}}{V_1} \right)$$

where  $V_1$  is the fundamental amplitude, and  $V_2$  through  $V_5$  are the amplitudes of the 2nd- through 5th-order harmonics.

# 10-Bit, 80Mps, Single 3.0V, Low-Power ADC with Internal Reference

Figure 12. Track-and-Hold Aperture Timing

## Spurious-Free Dynamic Range (SFDR)

SFDR is the ratio expressed in decibels of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest spurious component, excluding DC offset.

## Intermodulation Distortion (IMD)

The two-tone IMD is the ratio expressed in decibels of either input tone to the worst 3rd-order (or higher) intermodulation products. The individual input tone levels are at -6.5dB full scale, and their envelope is at -0.5dB full scale.
