

a

+15V, I²C Compatible
Digital Potentiometers

Preliminary Technical Data

AD5280/AD5282

FEATURES

256 Position
 AD5280 – 1-Channel
 AD5282 – 2-Channel (Independently Programmable)
 Potentiometer Replacement
 20K, 50K, 200K Ohm with TC < 50ppm/°C
 Internal Power ON Mid-Scale Preset
 +5 to +15V Single-Supply; ±5.5V Dual-Supply Operation
 I²C Compatible Interface

APPLICATIONS

Multi-Media, Video & Audio
 Communications
 Mechanical Potentiometer Replacement
 Instrumentation: Gain, Offset Adjustment
 Programmable Voltage to Current Conversion
 Line Impedance Matching

GENERAL DESCRIPTION

The AD5280/AD5282 provides a single/dual channel, 256 position digitally-controlled variable resistor (VR) device. These devices perform the same electronic adjustment function as a potentiometer, trimmer or variable resistor. Each VR offers a completely programmable value of resistance, between the A terminal and the wiper, or the B terminal and the wiper. The fixed A-to-B terminal resistance of 20, 50 or 200K ohms has a 1% channel-to-channel matching tolerance with a nominal temperature coefficient of 30 ppm/°C.

Wiper Position programming defaults to midscale at system power ON. Once powered the VR wiper position is programmed by a I²C compatible 2-wire serial data interface. Both parts have two programmable logic outputs available to drive digital loads, gates, LED drivers, analog switches, etc.

FUNCTIONAL BLOCK DIAGRAMS

The AD5280/AD5282 are available in ultra compact surface mount thin TSSOP-14/-16 packages. All parts are guaranteed to operate over the extended industrial temperature range of -40°C to +85°C. For 3-wire, SPI compatible interface applications, see AD5203/AD5204/AD5206/AD7376/AD8400/AD8402/AD8403/AD5260/AD5262/AD5200/AD5201 products.

ORDERING GUIDE

Model	Kilo Ohms	Temp	Package Description	Package Option
AD5280BRU20	20	-40/+85°C	TSSOP-14	RU-14
AD5280BRU50	50	-40/+85°C	TSSOP-14	RU-14
AD5280BRU200	200	-40/+85°C	TSSOP-14	RU-14
AD5282BRU20	20	-40/+85°C	TSSOP-16	RU-16
AD5282BRU50	50	-40/+85°C	TSSOP-16	RU-16
AD5282BRU200	200	-40/+85°C	TSSOP-16	RU-16

The AD5280/AD5282 die size is 75 mil X 120 mil, 9,000 sq. mil.
 Contains xxx transistors. Patent Number xxx applies.

NOTES:

- Typicals represent average readings at $+25^{\circ}C$, $V_{DD} = +5V$, $V_{SS} = -5V$.
- Resistor position nonlinearity error R-INL is the deviation from an ideal value measured between the maximum resistance and the minimum resistance wiper positions. R-DNL measures the relative step change from ideal between successive tap positions. Parts are guaranteed monotonic.
- $V_{AB} = V_{DD}$, Wiper (V_W) = No connect
- INL and DNL are measured at V_W with the RDAC configured as a potentiometer divider similar to a voltage output D/A converter. $V_A = V_{DD}$ and $V_B = 0V$. DNL specification limits of ± 1 LSB maximum are Guaranteed Monotonic operating conditions.
- Resistor terminals A,B,W have no limitations on polarity with respect to each other.
- Guaranteed by design and not subject to production test.
- Bandwidth, noise and settling time are dependent on the terminal resistance value chosen. The lowest R value results in the fastest settling time and highest bandwidth. The highest R value result in the minimum overall power consumption.
- P_{DISS} is calculated from $(I_{DD} \times V_{DD})$. CMOS logic level inputs result in minimum power dissipation.
- All dynamic characteristics use $V_{DD} = +5V$.
- See timing diagram for location of measured values.

OPERATION

The AD5280/AD5282 provides a single/dual channel, 256-position digitally-controlled variable resistor (VR) device. The terms VR and RDAC are used interchangeably throughout this documentation. To program the VR settings, refer to the Digital Interface section. Both parts have an internal power ON preset that places the wiper in mid scale during power on, which simplifies the fault condition recovery at power up. In addition, the shutdown $\overline{\text{SHDN}}$ pin of AD5280/AD5282 places the RDAC in a zero power consumption state where terminal A is open circuited and the wiper W is connected to terminal B, resulting in only leakage currents being consumed in the VR structure. In shutdown mode the VR latch settings are maintained, so that, returning to operational mode from power shutdown, the VR settings return to their previous resistance values.

Figure 4. AD5280/AD5282 Equivalent RDAC Circuit

PROGRAMMING THE VARIABLE RESISTOR
Rheostat Operation

The nominal resistance of the RDAC between terminals A and B are available in 20K Ω , 50K Ω , and 200K Ω . The final three digits of the part number determine the nominal resistance value, e.g. 20K Ω = 20; 50K Ω = 50; 200K Ω = 200. The nominal resistance (R_{AB}) of the VR has 256 contact points accessed by the wiper terminal, plus the B terminal contact. The eight bit data in the RDAC latch is decoded to select one of the 256 possible settings. Assume a 20K Ω part is used, the wiper's first connection starts at the B terminal for data 00_H. Since there is a 60 Ω wiper contact resistance, such connection yields a minimum of 60 Ω resistance between terminals W and B. The second connection is the first tap point corresponds to 138 Ω ($R_{WB} = R_{AB}/256 + R_W = 78\Omega + 60\Omega$) for data 01_H. The third connection is the next tap point representing 216 Ω ($78 \times 2 + 60$)

for data 02_H and so on. Each LSB data value increase moves the wiper up the resistor ladder until the last tap point is reached at 19982 Ω [$R_{AB} - 1\text{LSB} + R_W$]. The wiper does not directly connect to the B terminal. See Figure 4 for a simplified diagram of the equivalent RDAC circuit.

The general equation determining the digitally programmed output resistance between W and B is:

$$R_{WB}(D) = \frac{D}{256} \cdot R_{AB} + R_W \quad \text{eqn.1}$$

where D is the decimal equivalent of the binary code which is loaded in the 8-bit RDAC register, and R_{AB} is the nominal end-to-end resistance.

For example, $R_{AB} = 20\text{K}\Omega$, when $V_B = 0\text{V}$ and A-terminal is open circuit, the following output resistance values R_{WB} will be set for the following RDAC latch codes. Result will be the same if terminal A is tied to W:

D (DEC)	R_{WB} (Ω)	Output State
256	19982 Ω	Full-Scale ($R_{AB} - 1\text{LSB} + R_W$)
128	10060 Ω	Mid-Scale
1	138 Ω	1 LSB
0	60 Ω	Zero-Scale (Wiper contact resistance)

Note that in the zero-scale condition a finite wiper resistance of 60 Ω is present. Care should be taken to limit the current flow between W and B in this state to a maximum current of no more than 5mA. Otherwise, degradation or possible destruction of the internal switch contact can occur.

Similar to the mechanical potentiometer, the resistance of the RDAC between the wiper W and terminal A also produces a digitally controlled resistance R_{WA} . When these terminals are used the B-terminal should be let open or tied to the wiper terminal. Setting the resistance value for R_{WA} starts at a maximum value of resistance and decreases as the data loaded in the latch is increased in value. The general equation for this operation is:

$$R_{WA}(D) = \frac{256 - D}{256} \cdot R_{AB} + R_W \quad \text{eqn.2}$$

For example, $R_{AB}=20K\Omega$, when $V_A = 0V$ and B–terminal is open circuit, the following output resistance R_{WA} will be set for the following RDAC latch codes. Result will be the same if terminal B is tied to W:

D (DEC)	R_{WA} (Ω)	Output State
256	60	Full-Scale
128	10060	Mid-Scale
1	19982	1 LSB
0	20060	Zero-Scale

The typical distribution of the nominal resistance R_{AB} from channel-to-channel matches within $\pm 1\%$. Device to device matching is process lot dependent and is possible to have $\pm 30\%$ variation. Since the resistance element is processed in thin film technology, the change in R_{AB} with temperature has a **30 ppm/°C** temperature coefficient.

PROGRAMMING THE POTENTIOMETER DIVIDER Voltage Output Operation

The digital potentiometer easily generates output voltages at wiper-to-B and wiper-to-A to be proportional to the input voltage at A-to-B. Let's ignore the effect of the wiper resistance at the moment. For example connecting A–terminal to +5V and B–terminal to ground produces an output voltage at the wiper-to-B starting at zero volts up to 1 LSB less than +5V. Each LSB of voltage is equal to the voltage applied across terminal AB divided by the 256 position of the potentiometer divider. Since AD5280/AD5282 can be supplied by dual supplies, the general equation defining the output voltage at V_w with respect to ground for any given input voltage applied to terminals AB is:

$$V_w(D) = \frac{D}{256}V_A + \frac{256-D}{256}V_B \quad \text{eqn. 3}$$

where D is decimal equivalent of the binary code which is loaded in the 8-bit RDAC register.

Operation of the digital potentiometer in the divider mode results in a more accurate operation over temperature. Unlike the rheostat mode, the output voltage is dependent on the ratio of the internal resistors R_{WA} and R_{WB} and not the absolute values, therefore, the temperature drift reduces to 5ppm/°C.

DIGITAL INTERFACE

2-WIRE SERIAL BUS

The AD5280/AD5282 are controlled via an I²C compatible serial bus. The RDACs are connected to this bus as slave devices.

Referring from Figures 2 and 3, the first byte of AD5280/AD5282 is a Slave Address Byte. It has a 7-bit slave address and a R/W bit. The 5 MSBs are 01011 and the following

2 bits are determined by the state of the AD0 and AD1 pins of the device. AD0 and AD1 allow the user to use up to four of these devices on one bus.

The 2-wire I²C serial bus protocol operates as follows:

1. The master initiates data transfer by establishing a START condition, which is when a high-to-low transition on the SDA line occurs while SCL is high, Figure 2. The following byte is the Slave Address Byte which consists of the 7-bit slave address followed by an R/W bit (this bit determines whether data will be read from or written to the slave device).

The slave whose address corresponds to the transmitted address responds by pulling the SDA line low during the ninth clock pulse (this is termed the Acknowledge bit). At this stage, all other devices on the bus remain idle while the selected device waits for data to be written to or read from its serial register. If the R/W bit is high, the master will read from the slave device. On the other hand, if the R/W bit is low, the master will write to the slave device.

2. A Write operation contains an extra Instruction Byte more than the Read operation. Such Instruction Byte in Write mode follows the Slave Address Byte. The MSB of the Instruction Byte labeled A/B is the RDAC sub-address select. A “low” select RDAC1 and a “high” selects RDAC2 for dual channel AD5282. The 2nd MSB RS is the Mid-scale reset. A logic high of this bit moves the wiper of a selected RDAC to the center tap where $R_{WA}=R_{WB}$. The 3rd MSB SD is a shutdown bit. A logic high causes the RDAC open circuit at terminal A while shorting wiper to terminal B. This operation yields almost a zero Ohm in rheostat mode or zero volt in potentiometer mode. This SD bit serves the same function as the $\overline{SHDN}$ pin except it reacts in active low. The following two bits are O2 and O1. They are extra programmable logic output that users can make use of them by driving other digital loads, logic gates, LED drivers, and analog switches, etc. The 3 LSBs are DON'T CARE. See Figure 2.
3. After acknowledged the Instruction Byte, the last byte in Write mode is the Data Byte. Data is transmitted over the serial bus in sequences of nine clock pulses (eight data bits followed by an “Acknowledge” bit). The transitions on the SDA line must occur during the low period of SCL and remain stable during the high period of SCL, Figure 1.
4. In Read mode, the Data Byte goes right after the acknowledgment of the Slave Address Byte. Data is transmitted over the serial bus in sequences of nine clock pulses (slight difference with the Write mode, there are eight data bits followed by a “No Acknowledge” bit). Similarly, the transitions on the SDA line must occur during the low period of SCL and remain stable during the high period of SCL.
5. When all data bits have been read or written, a STOP condition is established by the master. A STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. In Write mode, the master will pull the SDA line high during the 10th clock pulse to establish a STOP

AD5280/AD5282

condition, Figure 2. In Read mode, the master will issue a No Acknowledge for the 9th clock pulse (i.e., the SDA line remains high). The master will then bring the SDA line low before the 10th clock pulse which goes high to establish a STOP condition, Figure 3.

A repeated Write function gives the user flexibility to update the RDAC output a number of times after addressing and instructing the part only once. During the Write cycle, each Data byte will update the RDAC output. For example, after the RDAC has acknowledged its Slave Address and Instruction Bytes, the RDAC output will update after these two bytes. If another byte is written to the RDAC while it is still addressed to a specific slave device with the same instruction, this byte will update the output of the selected slave device. If different instructions are needed, the Write mode has to start with a new Slave Address, Instruction, and Data Bytes again. Similarly, a repeated Read function of the RDAC is also allowed.

MULTIPLE DEVICES ON ONE BUS

Figure 5 shows four AD5282 devices on the same serial bus. Each has a different slave address since the state of their AD0 and AD1 pins are different. This allows each RDAC within each device to be written to or read from independently. The master device output bus line drivers are open-drain pull downs in a fully I²C compatible interface.

Figure 5. Multiple AD5282 Devices on One Bus

LEVEL SHIFT FOR BI-DIRECTIONAL INTERFACE

While most old systems may be operated at one voltage, a new component may be optimized at another. When two systems operate the same signal at two different voltages, proper method of level shifting is needed. For instance, one can use a 3.3V E²PROM to interface with a 5V digital potentiometer. A level shift scheme is needed in order to enable a bi-directional communication so that the setting of the digital potentiometer can be stored to and retrieved from the E²PROM. Figure 6 shows one of the techniques. M1 and M2 can be N-Ch FETs 2N7002 or low threshold FDV301N if V_{DD} falls below 2.5V.

Figure 6. Level Shift for different potential operation.

All digital inputs are protected with a series input resistor and parallel Zener ESD structures shown in figure 7. Applies to digital input pins SDA, SCL, and $\overline{\text{SHDN}}$.
