

16-Bit, High-Speed, 2.7V to 5.5V *microPower* Sampling ANALOG-TO-DIGITAL CONVERTER

Check for Samples: [ADS8317](#)

FEATURES

- **16 Bits No Missing Codes (Full-Supply Range, High or Low Grade)**
- **Very Low Noise: 5LSB_{PP}**
- **Excellent Linearity:**
 $\pm 0.8\text{LSB typ, } \pm 1.5\text{LSB max INL}$
 $+0.7\text{LSB typ, } +1.25\text{LSB max DNL}$
 $\pm 1\text{mV max Offset}$
 $\pm 16\text{LSB typ Gain Error}$
- ***microPower*:**
10mW at 5V, 250kHz
4mW at 2.7V, 200kHz
2mW at 2.7V, 100kHz
0.2mW at 2.7V, 10kHz
- **Packages: MSOP-8, SON-8**
- **Pin-Compatible with the [ADS8321](#)**
- **Serial (SPI™/SSI) Interface**

APPLICATIONS

- **Battery-Operated Systems**
- **Remote Data Acquisition**
- **Isolated Data Acquisition**
- **Simultaneous Sampling, Multichannel Systems**
- **Industrial Controls**
- **Robotics**
- **Vibration Analysis**

DESCRIPTION

The ADS8317 is a 16-bit, sampling, analog-to-digital (A/D) converter specified for a supply voltage range from 2.7V to 5.5V. It requires very little power, even when operating at the full data rate. At lower data rates, the high speed of the device enables it to spend most of its time in the power-down mode. For example, the average power dissipation is less than 0.2mW at a 10kHz data rate.

The ADS8317 offers excellent linearity and very low noise and distortion. It also features a synchronous serial (SPI/SSI-compatible) interface and a differential input. The reference voltage can be set to any level within the range of 0.1V to $V_{DD}/2$.

Low power and small size make the ADS8317 ideal for portable and battery-operated systems. It is also an excellent fit for remote data-acquisition modules, simultaneous multichannel systems, and isolated data acquisition. The ADS8317 is available in MSOP-8 and SON-8 packages. The SON package size is the same as a 3x3 QFN package.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

SPI is a trademark of Motorola, Inc.

All other trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ORDERING INFORMATION⁽¹⁾

PRODUCT	MAXIMUM INTEGRAL LINEARITY ERROR (LSB) ⁽²⁾	NO MISSING CODES ERROR (LSB)	PACKAGE-LEAD	PACKAGE DESIGNATOR	SPECIFIED TEMPERATURE RANGE	PACKAGE MARKING	ORDERING NUMBER	TRANSPORT MEDIA, QUANTITY

							ADS8317IBDRBR	Tape and Reel, 2500

(1) For the most current package and ordering information, see the Package Option Addendum located at the end of this data sheet, or see the TI website at www.ti.com.

(2) **Maximum Integral Linearity Error** specifies a 5V power supply and 2.5V reference voltage.

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

Over operating free-air temperature range (unless otherwise noted).

	ADS8317	UNIT
Supply voltage, V_{DD} to GND	–0.3 to +7	V
Analog input voltage ⁽²⁾	–0.3 to $V_{DD} + 0.3$	V
Reference input voltage ⁽²⁾	–0.3 to $V_{DD} + 0.3$	V
Digital input voltage ⁽²⁾	–0.3 to $V_{DD} + 0.3$	V
Input current to any pin except supply	–20 to +20	mA
Power dissipation	See Dissipation Ratings Table	
Operating virtual junction temperature range, T_J	–40 to +150	°C
Operating free-air temperature range, T_A	–40 to +85	°C
Storage temperature range, T_{STG}	–65 to +150	°C

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions is not implied. Exposure to absolute-maximum rated conditions for extended periods may affect device reliability.

(2) All voltage values are with respect to ground terminal.

Equivalent Digital Input/Output Circuit

TIMING INFORMATION

NOTE: (1) A minimum of 22 clock cycles are required for 16-bit conversion; 24 clock cycles are shown.

If $\overline{\text{CS}}$ remains low at the end of conversion, a new data stream is shifted out with LSB-first data followed by zeroes indefinitely.

NOTE: (2) After completing the data transfer, if further clocks are applied with $\overline{\text{CS}}$ low, the A/D converter will output zeroes indefinitely.

THEORY OF OPERATION

The ADS8317 is a classic Successive Approximation Register (SAR) analog-to-digital (A/D) converter. The architecture is based on capacitive redistribution that inherently includes a sample-and-hold function. The converter is fabricated on a 0.6 μ CMOS process. The architecture and fabrication process allow the ADS8317 to acquire and convert an analog signal at up to 250,000 conversions per second while consuming less than 10mW from V_{DD} .

Differential linearity for the ADS8317 is factory-adjusted via a package-level trim procedure. The state of the trim elements is stored in non-volatile memory and is continuously updated after each acquisition cycle, just prior to the start of the successive approximation operation. This process ensures that one complete conversion cycle always returns the part to its factory-adjusted state in the event of a power interruption.

The ADS8317 requires an external reference, an external clock, and a single power source (V_{DD}). The external reference can be any voltage between 0.1V and $V_{DD}/2$. The value of the reference voltage directly sets the range of the analog input. The reference input current depends on the conversion rate of the ADS8317.

The external clock can vary between 24kHz (1kHz throughput) and 6.0MHz (250kHz throughput). The duty cycle of the clock is not significant, as long as the minimum high and low times are at least 200ns ($V_{DD} = 4.75V$ or greater). The minimum clock frequency is set by the leakage on the internal capacitors to the ADS8317.

The analog input is provided to two input pins: +IN and -IN. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

The digital result of the conversion is clocked out by the DCLOCK input and is provided serially (most significant bit first) on the D_{OUT} pin.

The digital data that are provided on the D_{OUT} pin are for the conversion currently in progress—there is no pipeline delay. It is possible to continue to clock the ADS8317 after the conversion is complete and to obtain the serial data least significant bit first. See the *Digital Timing* section for more information.

ANALOG INPUT

The analog input is bipolar and fully differential. There are two general methods of driving the analog input of the ADS8317: single-ended or differential, as shown in Figure 37. When the input is single-ended, the -IN input is held at a fixed voltage. The +IN input swings around the same voltage and the peak-to-peak amplitude is $2 \times V_{REF}$. The value of V_{REF} determines the range over which the common voltage may vary, as shown in Figure 38 and Figure 39.

Figure 37. Methods of Driving the ADS8317—Single-Ended or Differential

Figure 38. Single-Ended 5V Input, Common Voltage Range vs V_{REF}

Figure 40. Differential 5V Input, Common Voltage Range vs V_{REF}

Figure 39. Single-Ended 2.7V Input, Common Voltage Range vs V_{REF}

Figure 41. Differential 2.7V Input, Common Voltage Range vs V_{REF}

When the input is differential, the amplitude of the input is the difference between the +IN and –IN input, or +IN – (–IN). A voltage or signal is common to both of these inputs. The peak-to-peak amplitude of each input is V_{REF} about this common voltage. However, since the inputs are 180° out-of-phase, the peak-to-peak amplitude of the difference voltage is $2 \times V_{REF}$. The value of V_{REF} also determines the range of the voltage that may be common to both inputs, as shown in [Figure 41](#) and [Figure 40](#).

In each case, care should be taken to ensure that the output impedance of the sources driving the +IN and –IN inputs are matched. If this matching is not observed, the two inputs could have different settling times. This difference may result in offset error, gain error, and linearity error that change with both temperature and input voltage. If the impedance cannot be matched, the errors can be lessened by giving the ADS8317 additional acquisition time.

The input current on the analog inputs depends on a number of factors: sample rate, input voltage, and source impedance. Essentially, the current into the ADS8317 charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance (24pF) to 16-bit settling level within 4.5 clock cycles. When the converter goes into the hold mode, or while it is in the power-down mode, the input impedance is greater than 1GΩ.

Care must be taken regarding the absolute analog input voltage. The +IN input should always remain within the range of GND – 300mV to $V_{DD} + 300mV$. The –IN input should always remain within the range of GND – 300mV to 4V. Outside of these ranges, the converter linearity may not meet specifications. To obtain maximum performance from the ADS8317, an input circuit such as that shown in Figure 42 is recommended.

Figure 42. Single-Ended and Differential Methods of Interfacing the ADS8317

REFERENCE INPUT

The external reference sets the analog input range. The ADS8317 operates with a reference in the range of 0.1V to $V_{DD}/2$. There are several important implications to this specification.

As the reference voltage is reduced, the analog voltage weight of each digital output code is reduced. This reduction is often referred to as the least significant bit (LSB) size and is equal to the reference voltage divided by 65,536. This relationship means that any offset or gain error inherent in the A/D converter appears to increase (in terms of LSB size) as the reference voltage is reduced. For a reference voltage of 2.5V, the value of the LSB is 76.3μV, and for a reference voltage of 1.25V, the LSB is 38.15μV.

The noise inherent in the converter also appears to increase with a lower LSB size. With a 2.5V reference, the internal noise of the converter typically contributes only 5LSB peak-to-peak of potential error to the output code. When the external reference is 1.25V, the potential error contribution from the internal noise is almost two times larger (9LSB). The errors arising from the internal noise are Gaussian in nature and can be reduced by averaging consecutive conversion results.

For more information regarding noise, consult Figure 18, *Peak-to-Peak Noise for a DC Input vs Reference Voltage*. Note that the Effective Number Of Bits (ENOB) figure is calculated based on the converter signal-to-(noise + distortion) ratio with a 2kHz, 0dB input signal. SINAD is related to ENOB as follows:

$$\text{SINAD} = 6.02 \times \text{ENOB} + 1.76$$

With lower reference voltages, extra care should be taken to provide a clean layout including adequate bypassing, a clean power supply, a low-noise reference, and a low-noise input signal. Due to the lower LSB size, the converter is also more sensitive to external sources of error, such as nearby digital signals and electromagnetic interference.

The equivalent input circuit for the reference voltage is presented in [Figure 43](#). At the same time, an equivalent capacitor of 24pF is switched. To obtain optimum performance from the ADS8317, special care must be taken in designing the interface circuit to the reference input pin. To ensure a stable reference voltage, a 47μF tantalum capacitor with low ESR should be connected as close as possible to the input pin. If a high output impedance reference source is used, an additional operational amplifier with a current-limiting resistor must be placed in front of the capacitors.

Figure 43. Input Reference Circuit and Interface

When the ADS8317 is in power-down mode, the input resistance of the reference pin has a value of 5GΩ. Because the input capacitors must be recharged before the next conversion starts, an operational amplifier with good dynamic characteristics, such as the [OPA350](#), should be used to buffer the reference input.

Noise

The transition noise of the ADS8317 itself is extremely low, as shown in [Figure 19](#) and [Figure 36](#); it is much lower than competing A/D converters. These histograms were generated by applying a low-noise DC input and initiating 8192 conversions. The digital output of the A/D converter varies in output code because of the internal noise of the ADS8317. This variance is true for all 16-bit, SAR-type A/D converters. Using a histogram to plot the output codes, the distribution should appear bell-shaped with the peak of the bell curve representing the nominal code for the input value. The $\pm 1\sigma$, $\pm 2\sigma$, and $\pm 3\sigma$ distributions represent 68.3%, 95.5%, and 99.7%, respectively, of all codes. The transition noise can be calculated by dividing the number of codes measured by 6, which yields the $\pm 3\sigma$ distribution, or 99.7%, of all codes. Statistically, up to three codes could fall outside the distribution when executing 1000 conversions. The ADS8317, with five output codes for the $\pm 3\sigma$ distribution, yields less than $\pm 0.8\text{LSB}$ of transition noise. Remember that to achieve this low-noise performance, the peak-to-peak noise of the input signal and reference must be less than 50μV.

Averaging

The noise of the A/D converter can be compensated by averaging the digital codes. By averaging conversion results, transition noise is reduced by a factor of $1/\sqrt{n}$, where n is the number of averages. For example, averaging four conversion results reduces the transition noise from $\pm 0.8\text{LSB}$ to $\pm 0.4\text{LSB}$. Averaging should only be used for input signals with frequencies near DC.

For AC signals, a digital filter can be used to low-pass filter and decimate the output codes. This configuration works in a similar manner to averaging; for every decimation by 2, the signal-to-noise ratio improves by 3dB.

DIGITAL INTERFACE

Signal Levels

The ADS8317 has a wide range of power-supply voltage. The A/D converter, as well as the digital interface circuit, is designed to accept and operate from 2.7V up to 5.5V. This voltage range accommodates different logic levels. When the ADS8317 power-supply voltage is in the range of 4.5V to 5.5V (5V logic level), the ADS8317 can be connected directly to another 5V, CMOS-integrated circuit. When the ADS8317 power-supply voltage is in the range of 2.7V to 3.6V (3V logic level), the ADS8317 can be connected directly to another 3.3V LVCMOS integrated circuit.

Serial Interface

The ADS8317 communicates with microprocessors and other digital systems via a synchronous 3-wire serial interface, as illustrated in the [Timing Information](#) section and [Timing Characteristics](#). The DCLOCK signal synchronizes the data transfer, with each bit being transmitted on the falling edge of DCLOCK. Most receiving systems capture the bitstream on the rising edge of DCLOCK. However, if the minimum hold time for D_{OUT} is acceptable, the system can use the falling edge of DCLOCK to capture each bit.

A falling $\overline{\text{CS}}$ signal initiates the conversion and data transfer. The first 4.5 to 5.0 clock periods of the conversion cycle are used to sample the input signal.

After the fifth falling DCLOCK edge, D_{OUT} is enabled and outputs a low value for one clock period. For the next 16 DCLOCK periods, D_{OUT} outputs the conversion result, most significant bit first. After the least significant bit (B0) has been output, subsequent clocks repeat the output data, but in a least significant bit first format.

After the most significant bit (B15) has been repeated, D_{OUT} will 3-state. Subsequent clocks have no effect on the converter. A new conversion is initiated only when CS has been taken high and returned low.

Data Format

The output data from the ADS8317 are in binary twos complement format, as shown in [Table 1](#) and [Figure 44](#). The table and figure represent the ideal output code for the given input voltage and do not include the effects of offset, gain error, or noise.

Table 1. Ideal Input Voltages and Output Codes

DESCRIPTION	ANALOG VALUE	DIGITAL OUTPUT BINARY TWOS COMPLEMENT	
		Binary Code	Hex Code
Full-scale range	$2 \times V_{\text{REF}}$		
Least significant bit (LSB)	$2 \times V_{\text{REF}}/65536$		
+Full scale	$+V_{\text{REF}} - 1 \text{ LSB}$	0111 1111 1111 1111	7FFF
Midscale	0V	0000 0000 0000 0000	0000
Midscale – 1 LSB	$0V - 1 \text{ LSB}$	1111 1111 1111 1111	FFFF
–Full scale	$-V_{\text{REF}}$	1000 0000 0000 0000	8000

Figure 44. Ideal Conversion Characteristics (Conditions: $V_{CM} = 2.5V$, $V_{REF} = 2.5V$)

POWER DISSIPATION

The architecture of the converter, the semiconductor fabrication process, and a careful design allow the ADS8317 to convert at up to a 250kHz rate while requiring very little power. However, for the absolute lowest power dissipation, there are several things to keep in mind.

The power dissipation of the ADS8317 scales directly with conversion rate. Therefore, the first step to achieving the lowest power dissipation is to find the lowest conversion rate that satisfies the system requirements.

In addition, the ADS8317 goes into Power-Down mode under two conditions: when the conversion is complete and whenever $\overline{CS}$ is high (see the Timing Characteristics section). Ideally, each conversion should occur as quickly as possible, preferably at a 6.0MHz clock rate. This way, the converter spends the longest possible time in power-down mode. This is very important because the converter not only uses power on each DCLOCK transition (as is typical for digital CMOS components), but also uses some current for the analog circuitry, such as the comparator. The analog section dissipates power continuously until power-down mode is entered.

Figure 9 and Figure 27 illustrate the current consumption of the ADS8317 versus sample rate. For these graphs, the converter is clocked at maximum speed regardless of the sample rate. $\overline{CS}$ is held high during the remaining sample period.

There is an important distinction between the power-down mode that is entered after a conversion is complete and the full power-down mode that is enabled when $\overline{CS}$ is high. $\overline{CS}$ low only shuts down the analog section. The digital section completely shuts down only when $\overline{CS}$ is high. Thus, if $\overline{CS}$ is left low at the end of a conversion, and the converter is continually clocked, the power consumption is not as low as when $\overline{CS}$ is high.

Short Cycling

Another way to save power is to use the $\overline{CS}$ signal to short-cycle the conversion. The ADS8317 places the latest data bit on the D_{OUT} line as it is generated; therefore, the converter can easily be *short-cycled*. This term means that the conversion can be terminated at any time. For example, if only 14 bits of the conversion result are needed, then the conversion can be terminated (by pulling $\overline{CS}$ high) after the 14th bit has been clocked out.

This technique can also be used to lower the power dissipation (or to increase the conversion rate) in those applications where an analog signal is being monitored until some condition becomes true. For example, if the signal is outside a predetermined range, the full 16-bit conversion result may not be needed. If so, the conversion can be terminated after the first n bits, where n might be as low as 3 or 4. This technique results in lower power dissipation in both the converter and the rest of the system because they spend more time in power-down mode.

POWER-ON RESET

The ADS8317 bias circuit is self-starting. There may be a static current (approximately 1.5mA with $V_{DD} = 5V$) after power-on, unless the circuit is powered down. It is recommended to run a single test conversion (configured the same as any regular conversion) after the power supply reaches at least 2.4V to ensure the device is put into power-down mode.

LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS8317 circuitry. This caution is particularly true if the reference voltage is low and/or the conversion rate is high. At a 250kHz conversion rate, the ADS8317 makes a bit decision every 167ns. That is, for each subsequent bit decision, the digital output must be updated with the results of the last bit decision, the capacitor array appropriately switched and charged, and the input to the comparator settled to a 16-bit level, all within one clock cycle.

The basic SAR architecture is sensitive to spikes on the power supply, reference, and ground connections that occur just prior to latching the comparator output. Thus, during any single conversion for an n -bit SAR converter, there are n windows in which large external transient voltages can easily affect the conversion result. Such spikes might originate from switching power supplies, digital logic, and high-power devices, to name a few potential sources. This particular source of error can be very difficult to track down if the glitch is almost synchronous to the converter DCLOCK signal because the phase difference between the glitch and DCLOCK changes with time and temperature, causing sporadic misoperation.

With these considerations in mind, power to the ADS8317 should be clean and well-bypassed. A 0.1μF ceramic bypass capacitor should be placed as close as possible to the ADS8317 package. In addition, a 1μF to 10μF capacitor and a 5Ω or 10Ω series resistor may be used to low-pass filter a noisy supply.

The reference should be similarly bypassed with a 47μF capacitor. Again, a series resistor and large capacitor can be used to low-pass filter the reference voltage. If the reference voltage originates from an op amp, make sure that the op amp can drive the bypass capacitor without oscillation (the series resistor can help in this case). Keep in mind that while the ADS8317 draws very little current from the reference on average, there are still instantaneous current demands placed on the external input and reference circuitry.

Texas Instruments' [OPA365](#) op amp provides optimum performance for buffering the signal inputs; the [OPA350](#) can be used to effectively buffer the reference input.

Also, keep in mind that the ADS8317 offers no inherent rejection of noise or voltage variation in regards to the reference input. This characteristic is of particular concern when the reference input is tied to the power supply. Any noise and ripple from the supply appears directly in the digital results. While high-frequency noise can be filtered out, as described in the previous paragraph, voltage variation resulting from the line frequency (50Hz or 60Hz) can be difficult to remove.

The GND pin on the ADS8317 should be placed on a clean ground point. In many cases, this point is the analog ground. Avoid connecting the GND pin too close to the grounding point for a microprocessor, microcontroller, or digital signal processor. If needed, run a ground trace directly from the converter to the power-supply connection point. The ideal layout includes an analog ground plane for the converter and associated analog circuitry.

APPLICATION CIRCUITS

Figure 45 shows an example of a basic data acquisition system. The ADS8317 input range is connected to 2.5V or 4.096V. The 5Ω resistor and 1μF to 10μF capacitor filters the microcontroller noise

on the supply, as well as any high-frequency noise from the supply itself. The exact values should be picked such that the filter provides adequate rejection of noise. Operational amplifiers and voltage reference are connected to the analog power supply, AV_{DD} .

REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision C (June 2008) to Revision D	Page
• Changed SON-8 (DRB) package availability	1
• Deleted lead temperature specification	2
• Added missing μ symbol to High-level output voltage test condition	4
• Added missing μ symbol to Low-level output voltage test condition	4
• Changed X-axis unit from mA to μ A in Figure 10	11
• Changed Figure 38	17
• Changed Figure 39	17
• Changed Figure 40 title (typo)	17
• Added missing μ symbol to the value of the LSB, 76.3V	18
Changes from Revision B (May 2008) to Revision C	Page
• Changed 2nd timing diagram from the top in Figure 1	8

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

PLASTIC SMALL OUTLINE

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
 - B. This drawing is subject to change without notice.
 - C. Small Outline No-Lead (SON) package configuration.
 - The package thermal pad must be soldered to the board for thermal and mechanical performance. See the Product Data Sheet for details regarding the exposed thermal pad dimensions.
 - Metalized features are supplier options and may not be on the package.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

Bottom View

NOTE: All linear dimensions are in millimeters

Exposed Thermal Pad Dimensions

DRB (S-PVSON-N8)

- NOTES:
- All linear dimensions are in millimeters.
 - This drawing is subject to change without notice.
 - Publication IPC-7351 is recommended for alternate designs.
 - This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, QFN Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>.
 - Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
 - Customers should contact their board fabrication site for solder mask tolerances.

DGK (S-PDSO-G8)

PLASTIC SMALL-OUTLINE PACKAGE

NOTES:

- A. All linear dimensions are in millimeters.
- B. This drawing is subject to change without notice.
- C. Body length does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 per end.
- D. Body width does not include interlead flash. Interlead flash shall not exceed 0.50 per side.
- E. Falls within JEDEC MO-187 variation AA, except interlead flash.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
